sunshine; and sedentary occupations, particularly in over-heated and crowded apartments or factories, more or less predispose the female constitution to this affection. Some writers believe that the use of tea and coffee has a similar effect; it is possible that the former, especially green tea, taken too frequently or in excess, will weaken the nervous system; and that the latter will sometimes excite the uterine organs. The influence of *climate* is not very manifest; temperate and changeable regions certainly furnish more numerous instances of nervous disorder in females, than very warm or very cold countries; but as much is probably owing to the state of *manners* and *society* in the former, as to climate. Even *dress* has some effect in the production of hysteria; inordinate compression of the waist by stays not only weakens and displaces the digestive organs, but favours local determinations and congestions, and deranges the uterine functions.

51. *d. Previous disorder* more frequently predisposes to hysteria, than other circumstances, for many of those already noticed induce other complaints, before hysteria, in any of its forms, is manifested; and these complaints constitute merely that state of predisposition, which only requires the occasion or exciting cause of its appearance. The various disorders of MENSTRUATION (see that article), determination of blood to, or congestion, or irritation of any of the uterine organs, may exist, and yet no hysterical affection take place. The nervous system also, both ganglial and cerebro-spinal, may be susceptible and morbidly sensible, and yet none of the phenomena constituting hysteria may appear. These, as well as some other morbid states, frequently constitute only the predisposition, which, however, will readily burst into open disease, when one or more of the exciting causes come into operation. Whatever exhausts organic nervous power will increase susceptibility and irritability, and thus constitute that mobility of the system, and disposition to local determinations and congestions, justly insisted upon by Dr. CULLEN, as being connected with the pathology of the complaint. The susceptibility arising from exhaustion by acute disease favours the appearance of hysteria, especially during early convalescence. The approach and presence of the catamenia have also some influence, both as a predisposing and an exciting cause.

52. *Gastro-intestinal disorder*, or irritation, has been justly viewed by numerous writers, as a predisposing cause of hysteria, and particularly insisted upon by BROUSSAIS and his followers. Although this writer has doubtless exaggerated the influence of this morbid condition, and imputed to it phenomena depending chiefly on debility and augmented organic nervous sensibility, yet it is nevertheless often present, associated, however, with other morbid states, as those just named, and with impaired action and flatulent distention of the digestive canal. In some cases also, the gastro-intestinal disorder is almost coeval with, and purely a complication of, the hysterical affection. But it is much more frequently observed, that numerous circumstances tending to disorder the digestive mucous surface, especially errors in diet, as respects both food and drink, and various symptoms indicating impaired or disordered digestion and fæcation, have preceded for a longer or shorter period the development of the hysterical disorder. Still it must be admitted, that the symptoms referred to the alimentary canal, especially impaired function, flatulent distention and borborygmi, and altered sensibility, are greater indications of debility of the organic nervous system, than of inflammatory irritation of the gastro-intestinal mucous membrane. Nor should it be overlooked, that disorder of the uterine organs, seated not merely in the nerves, but affecting also vascular action in these organs, may exist without exciting painful sensations, and yet sympathetically disturb the digestive canal. Thus we perceive the changes produced in the uterine system by impregnation displayed chiefly in the digestive organs and nervous system. Even the errors of diet, and the desire for various improper or indigestible articles of food and drink, which has been attributed to disorder of the alimentary canal, may be actually occasioned by changes originating in the uterine organs. These substances, however, by increasing the disorder of the digestive tube, will aggravate or perpetuate the primary affection of the sexual organs. There can be no doubt, that whatever weakens organic nervous power, as all disorders of the gastro-intestinal viscera necessarily do, will both dispose to, and increase, hysterical complaints.

53. It has been supposed by some writers, that the females of *gouty* parents are more prone than others to hysteria. This may be partly accounted for, by deficiency of constitutional energy derived from the parent, and greater susceptibility of the nervous system, as well as by the circumstances alluded to above (§ 49.).

54. ii. *Exciting Causes.* — Certain of the predisposing causes may of themselves occasion the complaint, when more than usually active, especially disorder of the uterine organs, or of the digestive canal. Excitement of the nerves of the uterus or ovaria, or irritation of them, particularly in connection with any irregularity of menstruation; inflammatory action, of an acute, subacute, or chronic nature, of the vagina, or of these organs; congestion, structural lesion, tumours, polypi, &c., of the uterus, and leucorrhœa, not infrequently occasion hysteria. Although this disorder is very often connected with excitement, or even with inflammatory irritation in the ovaria, yet it is seldom symptomatic of fully developed ovarian dropsy. It is not improbable, that this latter malady proceeds from a state of impaired tone, or is associated with a condition of the organic actions in these parts, incompatible with the production of the hysterical paroxysm. Irritation of the gastro-intestinal mucous membrane, by stimulating or acrid ingesta, particularly such as act upon the colon and rectum, as large doses of aloes, colocynth, &c.; morbid secretions, mucous sordes, and fæcal collections in the large bowels; the irritation of worms, especially of ascarides, in the rectum—the *Hysteria verminosa* of SAUVAGES; the use of stimulating or acrid glysters; and hæmorrhoids, sometimes excite one or other of the forms of the complaint. Excessive discharges and hæmorrhages, particularly prolonged leucorrhœa, diarrhœa, abortions, uterine hæmorrhage, and protracted suckling, on the one hand; and on the other, the suppression of discharges, as of the catamenia, of the lochia, and of leucorrhœa; long or extreme suffering from pain; mental or bodily

fatigue; and even irritation of remote parts, as that connected with cutting the wisdom teeth, occasionally induce a seizure.

55. Mental affections and excitements, especially those which act upon the uterine system in particular, disappointments in love, unreturned and spurned affections, jealousy, anger and other violent emotions; protracted expectation, longings after objects of desire, tragic representations, frights, the sight of objects, disgusting or distressing, or disagreeable from peculiar mental diathesis, and intelligence of a distressing or of an exciting nature, suddenly communicated, are the most common occasions of hysteria, as respects both its first appearance, and its subsequent recurrences. Several of these emotions affect the uterine organs, the affection being afterwards reflected upon the nervous system generally. Premature or physically incongruous marriages; excited, but unsatisfied, desires; celibacy, and veneris desiderium inane, are also not infrequent causes of the complaint. Frank remarks, that "Cœlibem vitam plures sine noxâ ducere possunt fœminæ, sed vix unam illarum invenies, quæ prope maritum impotentem impune decumbere possit. Idem de uxoribus, a maritis neglectis, valet."— There is no doubt, that the sight of others in the fit will sometimes produce an hysterical seizure. I have myself witnessed this on two or three occasions; and in one of these, two females were attacked from this circumstance. This phenomenon has been imputed to imitation; but it may with equal propriety be assigned to sympathy, to fear, &c. Probably more than one of these feelings are concerned in producing it. Severe mental distresses, or extreme joy, may also occasion some one or other of the forms of the complaint. Immoderate fits of laughing produced by humorous or ridiculous occurrences, or crying caused by vexation or contrarieties, may also pass into the hysterical paroxysm. I have no doubt of the fit being often renewed at pleasure, almost as readily as tears may be shed, by recalling or adverting to various feelings, emotions, or circumstances; and I have even seen instances which have convinced me of the fact. Electrical and warm states of the air, and sudden vicissitudes of temperature, have been supposed sufficient to produce a seizure. The influence of spirituous or vinous potations, of stimulating diuretics, and of substances which excite or irritate the urinary bladder, in the production of the complaint, is much less doubtful than that of atmospheric temperature; but the close, warm, and impure air of crowded rooms and assemblies, particularly in connection with excited feelings or contrarieties, very often occasions an attack, especially in those who have previously experienced it. A similar effect is in rarer instances produced by various odours, especially in peculiar idiosyncracies. Highmore states that the fit has been often induced by the odour of musk.

56. IX. Pathology.— The nature of hysteria may be in a great measure inferred from what has already been stated respecting its symptoms and causes; yet something more explicit still must be advanced on this subject. As simple and pure hysteria is rarely or almost never fatal, and as we therefore have hardly ever an opportunity of examining the state of the principal viscera of patients who had been subject to this complaint, unless they have died of some intercurrent or associated malady, so proofs have been wanting in support of any of the doctrines proposed as to its nature, and a very wide scope allowed for vague hypothesis. The ancients and many of the moderns referred hysteria to the womb; and hence the origin of the name. The ancients, however, ascribed properties, powers, functions, and motions to the uterus, which modern knowledge has shown to be erroneous; yet I am disposed to believe that this organ, influenced as it most probably is by the nervous and vascular states of the ovaria, performs a very important part in the œconomy; and that this is not confined to alterations merely of its organic sensibility, but that it extends frequently to its contractility, and to several related organs.

57. Some recent writers have ascribed hysteria to irritation in the uterus, in the intestines, in the brain, or even in other internal viscera, occurring in delicate, nervous, or susceptible persons. Dr. Conolly remarks, that in all cases of hysteria there is a disordered state of some part or the whole of the nervous system; and that, although this state may be, and very frequently is, induced by uterine irritation, it no less evidently arises, in other cases, from causes productive of irritation in other parts of the body, and also from causes acting directly upon the mind. That more or less susceptibility, original or acquired, characterises the state of the nervous system in hysterical persons will not be disputed; yet even in such persons, the usual exciting causes, or irritations of different viscera, will not occasion true hysterical symptoms, unless they previously affect the state of organic nervous influence, or of circulation, in the sexual organs.

58. Willis ascribed hysteria to disorder of the brain, and M. Georget has recently adopted the same view, which has been most ably and satisfactorily overthrown by M. Foville. Still more recently Mr. Tate has contended that hysteria arises from a morbid state of the spinal cord, connected with disorder of the womb; but, as I have already remarked, this "morbid state" is but a vague generic term, and that, most probably, even when it is most prominent, more of altered sensibility than of vascular or structural lesion, of this part of the nervous system constitutes its essence. However this may be, attentive observation of the morbid phenomena, especially at their commencement, will show that the spinal affection is merely a consecutive and contingent disorder, and one by no means generally, or even very frequently, observed. This want of precision in the use of terms, and in the ideas relating to the pathology of hysteria has been surpassed by M. Andral, when he says, "As to my opinion respecting the seat of hysteria, I repeat, that it is a nervous complaint, and that its seat is the nervous system!"

59. Although the uterus and its appendages have been viewed as the chief source of hysteria, both by the ancients, and by most of the moderns, yet some difference of opinion exists as to the nature of this primary affection. Pinel, Villermay, Lobstein, and Foville consider that it is entirely nervous, or is an excited state of the nerves supplying the organs of generation. Other writers, as Addison, &c., who have adopted the term uterine irritation, seem to ascribe to this

term a similar meaning to that which the above authors have wished to convey; although they contend, that, in connection with this state, the uterine functions are very often disordered. M. Pujol, on the other hand, infers the existence of chronic inflammatory action of the uterus, as the immediate cause of the complaint. Inflammatory action in its various grades, from simple erethysm upwards to the most acute vascular change, may sometimes be a complication or cause of hysteria; but there is no necessery dependence of the one upon the other; for we often meet with *metritis*, without hysterical symptoms, and still more frequently with fully developed hysteria, without any evidence of metritis. Yet it should not be overlooked that the former is often symptomatic of, or complicated with, the latter.

60. When we consider the number and importance of the nerves of the female organs of generation; the connections existing between them and the nerves supplying the kidneys, the urinary bladder, and the intestinal canal on the one hand, and the spinal and sacral nerves on the other; and the fact that these nerves are small and apparently few in girls, large and numerous during the epoch of uterine activity, and very small in old women; the sympathetic effects of irritation, excitement, or of erethysm of them will be more readily recognised, and the relation of these sympathies to their source made more obvious. Attentive observation of the causes of hysteria, and of their more immediate effects upon the generative system, and a knowledge of the sensations of the patient with reference to the origin and course of this ailment, will prove, that the old opinion as to its source is correct. That the primary affection is seated in the nerves of the generative organs, and that it consists chiefly of excitement, erethysm, or irritation, sometimes, however, associated with congestion or vascular determination to the uterus, or with disorder of the catamenia, are shown by the circumstances in which it is observed, and the fact that it never appears until these nerves have approached their full development, nor after their principal functions have ceased. Georget, however, contends in opposition to this opinion, that organic lesions of the uterine organs are very common in females, who have never had hysteria; and that the more serious changes, as cancer uteri, uterine polypi, ovarian dropsy, &c., are seldom accompanied with this complaint. But the most of these maladies do not appear during the epoch, in which hysteria is most common. As long as the uterine functions and sympathies are active, hysteria will occur. Hence its not infrequent connection with metritis and other uterine diseases, during the prime of life; but when these functions and sympathies are exhausted or greatly enfeebled, as in most of the dangerous maladies and organic lesions of the uterus and ovaria, as well as in advanced life, hysteria will not be developed. The generative nerves have then become incapable of experiencing that state, and of exerting that influence upon the nerves related to them, which are requisite to the production of hysterical phenomena. As M. Foville has justly observed, we do not find sexual ardour amongst the symptoms of malignant alterations of the testes, or of hydatids in the spermatic cord, &c. Hysteria does not occur in aged females, for the very same reason that menstruation and pregnancy do not take place in them. The belief that hysteria may affect males has been adduced against its uterine origin; but the fact of true or unequivocal hysteria having been met with in males, needs further confirmation; or rather the nervous affections, resembling some states of hysteria, noticed in this sex, require a closer observation than they have hitherto received. I will not, however, deny, that irritation of the male sexual organs will not occasionally produce disorder, in many respects similar to that observed in females in like circumstances, particularly in susceptible and nervous persons.

61. My views, therefore, as to the *pathology of hysteria* are as follows: — *a*. That hysteria arises from the state of the organic nervous influence endowing the generative organs of the female, and that a similar state of the sexual organs of the male very rarely occasions it, and then only in peculiar circumstances; — *b*. That this state of nervous influence nearly approaches to, or consists of, excitement, nervous erethysm or irritation, or is of an active or sthenic kind, as respects the functions of these organs; — *c*. That this is generally attended by vital turgescence of the vessels of the uterine system; and these states, consequently, occur chiefly during the prime of life, or whilst the nerves of generation and the uterine circulation possess their functional energies; — *d*. That these conditions of nervous influence and circulation in these organs are generally insufficient of themselves to occasion the fully developed complaint; and that, in addition, there are increased sensibility and irritability of the sentient and motive systems, and consequently augmented susceptibility of impressions, from mental or physical causes, arising either from original conformation, or from acquired habit or diathesis; — *e*. That when these states of the generative organs are excited by mental emotions or by other circumstances, the affection is propagated by direct or immediate sympathy, — by the organic nerves, — to the digestive tube and urinary organs on the one hand, and to the cerebro-spinal nervous system on the other; and thus the phenomena constituting the hysterical seizure are developed; — *f*. That the hysterical phenomena, proceeding from *direct sympathy* with the uterine organs, consist chiefly of those referred to the bowels — the borborygmi, globus, &c., and to the urinary organs, as the increased secretion of urine, &c.; — *g*. That the extension of the disorder of the uterine nerves, by means of the ganglial system and its communicating branches, to the roots of the spinal nerves, gives rise to the symptoms depending upon *reflex sympathy* *, especially the convulsions, pains, &c., and the affections of the respiratory organs, throat, head, &c.; — *h*. That the phenomena of the developed states of the disease and of its irregular forms are principally sym-

---

* In my Appendix *to* M. Richerand's *Elements of Physiology*, published in 1824 and in 1829, I have divided the sympathies into — 1st. The *Reflex*, or those which take place in consequence of irritations conveyed by the nerves to the cerebro-spinal centres, and thence reflected upon motive or sentient parts: — and, 2dly. The *Direct*, or those which proceed more immediately from the seat of primary excitement to other parts, by means chiefly of nervous communication, continuity of membrane, structure, &c. — These views as to sympathy, which are certainly original, were applied to the explanation of the pathology of Chorea, and its related disorders of Convulsions, Epilepsy, &c.

pathetic, and of the kind which I was the first to denominate the *reflex* (see *Notes and Appendix to* RICHERAND's *Elements of Physiology*, pp. 34. and 546.); and the same views and pathological explanations given in the articles CHOREA AND RELATED AFFECTIONS (§ 15—17.), CONVULSIONS (§ 46.), EPILEPSY (§ 51.), apply to the different varieties of HYSTERIA; — *i.* That, although hysteria is often connected with deficient or irregular menstruation, yet this function is sometimes excessive, or is occasionally regular, in every respect, in hysterical persons.

62. X. TREATMENT. — There are few diseases less under the control of medical treatment than hysteria; and various circumstances connected with it often occur to render the management of it not only unsatisfactory, but also unpleasant. Patients themselves or their friends readily suppose that relief should quickly follow a recourse to medicine, and conclude, that the proper means have not been employed, when relief is not obtained. They do not consider, — and the fact is generally not sufficiently explained in the proper quarter, and at the proper time, — that the complaint arises from causes which are mostly permanent in their action, or which continue during the treatment, and that in every case the difficulty of removing an effect, whilst the causes are in operation, is very great. The candid physician also readily admits, that the complaint in its various forms is devoid of danger, and this circumstance is believed by many to imply a speedy cure. Several varieties of it also are calculated to excite alarm; and, if they be not soon removed, the knowledge or ability of the physician, under whose care they may have come, is impeached; and some other advice is asked, and often in quarters noted neither for honesty nor ability. If the patient should thus fall into the hands of either the qualified or the unqualified charlatan, the complaint is misrepresented or exaggerated, and alarm is excited. The effect, however, is often beneficial, although it was as little intended as its source was unsuspected. The impression of fear on the mind may put a stop to some of the causes, or may interrupt the succession of morbid sympathies. The patient, moreover, after she has passed from the care of the scientific practitioner, may be subjected to influences of a powerful nature, moral or physical, or both, and experience temporary or some permanent advantages from them; but from whatever source they proceed, or by whomsoever administered, — whether by the medical empiric, or by the spiritual comforter — the modern worker of miracles, — the results are often equally annoying to the duly qualified practitioner. The regular professor of medicine is expected to administer benefit in all cases, and without regard to circumstances. If he fail, and the patient, under very different circumstances and influenced by very different feelings, receive benefit from the manipulations of a charlatan, whose means are more striking or imposing, or more suited to the moral condition of the patient, than those previously employed, the occurrence is made a matter of notoriety, and equally to the disadvantage of the one, as to the credit of the other. The former is expected by the public to cure, and it is considered discreditable for him to fail; the latter is viewed as having made a wonderful discovery, if he succeed but in a single case, and his knowledge is supposed to have come by inspiration, as it could not have been derived from any other source. Another circumstance further serves to counteract the treatment advised by scientific men, particularly in large towns. The patient is capricious, and her friends are often equally unstable. If benefit is not received in a very short time, the advice of some one else is obtained, and before he can be of any service, he also is dismissed, and a third is called in. Thus, from twenty to thirty practitioners may be consulted without one of them having had a sufficient opportunity of fulfilling a single intention of cure. Now, what is the consequence? The patient resorts to some noted or fashionable empiric, who is informed of her long sufferings, and the want of success of the greatest physicians in her case. He is shrewd enough to see at once the state of matters, and to turn them both to his pecuniary advantage and to his credit. He exaggerates the risk, the difficulty, and the consequences of the disease; refuses to undertake the case, unless at his own terms, which he takes care to secure; and he thus also secures the continuance of the patient under his care, and even her confidence, although he should fail in all beside.

63. From the dishonest acts of charlatans, useful lessons may, however, be honestly learnt. When a physician is called to a nervous patient, who has been under the care of other physicians, instead of prescribing at once, and without reference to this circumstance, he should acquaint her or her friends, that probably a sufficient opportunity of affording relief had not been allowed to those who had preceded him; that, as a member of an honourable profession, he expects to be honourably dealt with, and that he will not compromise his reputation by prescribing for the case, unless he be allowed time and opportunity — fully and circumstantially — for its proper treatment. Unless these be conceded, and in a spirit which will promise to secure their due performance, it will be infinitely better to relinquish the case altogether, than to enter upon the treatment of it, with the probability of disappointment. When it is found that the physician thus regards his own reputation, respect and confidence will be accorded to him by the patient and her friends.

64. There are various circumstances in the pathology of hysteria, which require strict attention in the treatment. — 1st. The particular form of the hysterical seizure, whether regular, irregular, or anomalous; — 2d. The condition of the nervous system, particularly with reference to increased sensibility and irritability; — 3d. The excitement, erethysm, vital turgescence, or other disorder of the uterine system, and their influence by *direct* and *reflex sympathy*; — 4th. The states of the vascular system, in connection with these, especially in respect of *plethora*, general or local, or of deficiency of blood; — and, 5th. The functional or other disorder of the digestive canal. Of all these, the most important is the state of uterine function; for unless the symptoms connected with the generative organs be carefully ascertained, as far as is proper to inquire, and the disorder in this quarter be carefully inferred, the treatment will often be unsuccessful; and, even with the utmost exercise of professional acumen, we may fail, more or less, owing to the permanence of the moral and physical causes of the complaint.

65. i. Treatment in the Seizure. — *A.* If the paroxysm be attended by severe *convulsions*, the principal intention is, *to preserve the patient from injuring herself*; the next is, *to shorten its duration.* — *a.* Although her struggles are severe, she generally retains sufficient consciousness and even volition, to avoid danger. Therefore little effort should be made to restrain them, and especially as they have upon the whole a beneficial effect, particularly in equalising the circulation. If, however, the fit assumes an epileptic character, this object should be carefully attended to, and a folded napkin placed between the teeth, if it be required. In all cases, the patient should be removed to an airy apartment, and the clothes loosened around the waist, chest, and neck. — *b.* In order to *shorten the fit*, various means have been recommended, and found more or less serviceable. If the patient is able to swallow fluids, a large cup full of *cold or iced water* may be given and repeated. If the seizure be more severe, or be attended by general or cerebral plethora, the *affusion of cold water* on the head and neck should be resorted to, or cloths wet with it, or with an evaporating lotion, should be placed around the head. If the severity of the spasms, particularly of the muscles of the face and jaws, and of the strangulating sensation arising from the globus, prevents deglutition, *enemata* will be found of great service. The substances which I have found most efficacious, when thus employed, are, the spirits of *turpentine* alone, or with castor or olive oil, *assafœtida*, and *camphor*. An enema of the coldest spring water also puts an instant stop to the convulsions. The spirit of turpentine was recommended by me in 1821 (*Med. and Phys. Journ.* vol. xlvi. p.107.185.), in these cases. From half an ounce to an ounce and a half of it, may be thus administered, with either of the oils just named, in any vehicle, as gruel, milk, broth, &c. As the patient's consciousness is seldom lost in the seizure, the influence of fear in arresting it has been often resorted to, and frequently with complete success. Even mention of the affusion of cold water has put a stop to the fit. Yet instances have occurred in timid persons of great nervous susceptibility, where fear has aggravated the convulsions.

66. *B.* Where there is neither cerebral plethora nor difficult deglutition, the internal use of *diffusible stimulants*, as the preparations of *æther*, of *ammonia*, of *valerian*, of *assafœtida*, &c., have been very generally recommended, and are often useful, combined, according to circumstances, with one another, or with *anodynes*, as *laudanum*, *henbane*, *hydrocyanic acid*, &c.; the smoke of burnt feathers, and the odour of assafœtida, of mint, of the volatile alkali, of aromatic vinegar, &c., are the common domestic means for the removal and prevention of a seizure. Much, however, particularly as respects the *prevention* of the fit, depends upon the patient herself. Most females, subject to the complaint, give way to the current of their feelings, until the paroxysm is developed, although a determined resolution to prevent or suppress it would often prove successful. Diffusible stimulants are not so generally useful in preventing, as in shortening, the attack. The former of these objects is more certainly obtained by a draught of cold water, or by an enema of the same, or by cold applications to the head, than by other means. Dr. Conolly states that he has found half a drachm of ipecacuanha prevent the seizure. Any of the other substances already recommended to be used in enemata, for the purpose of shortening the fit, will generally also prevent it.

67. *C.* The more severe or alarming states of the fit, as the comatose, the cataleptic, &c., are most benefited by the affusion of cold water on the head, or by the application of cold lotions in this quarter. Vascular *depletions* are seldom necessary during the fit, even in these cases, unless the attack has followed the suppression of accustomed discharges; or the temperature of the head, and the action of the carotids show the propriety of prescribing them, and even then a moderate bloodletting, or cupping on the nape of the neck, will be sufficient. Warm and rubefacient *pediluvia*, and other *derivatives* from the head, may also be employed in these cases. The means which may be further resorted to will be stated hereafter (§ 71. 75. 97.).

68. ii. General Treatment, particularly in the Intervals. — *A. With reference to the state of the uterine system.* — The female organs of generation may be subject to that state of excitement, erethysm, turgescence, or irritation, which, in susceptible and nervous persons, seems intimately connected with hysteria, without the catamenia being in any way disordered. More commonly, however, this discharge is scanty, difficult, painful, or irregular as to time, quantity, and character. In a few instances it is suppressed, or nearly so; in others it takes place at intervals of two or three months; in some it is too profuse, or much too frequent, and in many it is pale and branniform, or it presents appearances more fully described in the article Menstruation. But all these states are usually accompanied by more or less of altered sensibility, referrible to the uterus or ovaria: there is often pain behind or above the pubis, in the lower part of the sacrum, or in the loins, or in the hips or tops of the thighs; the excretion of urine is disturbed, or too frequent, or attended by slight scalding, &c.; and there is sometimes leucorrhœa, with tenderness of the os uteri on examination, and occasionally an unpleasant sense of heat in the vagina. All these indicate the propriety of having recourse to local depletions; yet, unless the patient be plethoric, or the discharge has been scanty or suppressed, a very copious vascular depletion is often injurious. A moderate *cupping* on the sacrum; or the application of ten or twelve *leeches* to the groins, two or three days before the expected return of each monthly evacuation, or to the hypogastrium, will generally suffice. If the depletion be more liberal, the employment of tonics and of other means to improve the general health must not be neglected.

69. All the symptoms just noticed as indicating irritation of the uterus, are often present, even in the severest form, where there is great constitutional debility, and, in a few instances, where the colour of the surface and of the lips, and the states of the pulse and of the veins, indicate more or less anæmia. In these, even local depletions may be hurtful. The chief dependence must therefore be placed in preventing local excitement or irritation, in the use of cooling *tonics* sometimes in conjunction with *anodynes* and *sedatives*; and in improving the digestive functions and general health, by

suitable diet and regimen. The *sulphates of iron*, of *zinc*, and of *quinine*, are severally of use, in combination with small doses of *camphor*, or of *ipecacuanha*, and with *extract of henbane*, or of *hop*. If these should occasion headach, or increase the tenderness in the vicinity of the uterus, the *infusion* or *decoction of cinchona*, or the *infusion of valerian* with *nitrate of potash*, or *hydrochlorate of ammonia*, or carbonate of *soda*, may be prescribed. When the bowels require to be opened, the *cooling aperients*, as the bitartrate of potash, with the nitrate, and the confection of senna, should be preferred. Moral and physical *quietude*, frequent reclining on a couch, and a digestible and cooling diet, ought also to be enforced. In more plethoric persons, these means are still more requisite than in the preceding; and, instead of chalybeates and tonics, *cooling diaphoretics*, particularly weak camphor mixture, with solution of the acetate of ammonia, nitrate of potash, and spirits of nitric æther, will be often taken with benefit. Wherever uterine turgescence or erethysm is inferred, the treatment must be directed with reference to the states of general or local plethora, and of nervous power, as hereafter insisted upon; and hot spices, exciting articles of food, and stimulating beverages, should be avoided. Heating purgatives and irritating injections ought not to be employed. A separate sleeping apartment should be suggested.

70. When the catamenia are disordered, the treatment must be directed with strict reference to the state of disorder, as explained in the article Menstruation. If they be *excessive* or *too frequent*, *tonics* and *astringents*, with *refrigerants*, and *anodynes* or *narcotics*, are generally requisite; but the predominant use of either of these classes of remedies should depend upon the peculiarities of the case In these cases especially, advantage will accrue from *cold sponging* the loins, abdomen, and hips, every morning with an *astringent lotion*, as with equal parts of rose water, solution of the acetate of ammonia, and vinegar; from the occasional recourse to an *enema of cold water*, particularly when a seizure is threatened, or to *emollient* and *anodyne enemata* on other occasions; and from rest in the horizontal posture. The *cold plunge* or *salt-water bath*, or *shower bath*, will often also be of service. In the other states of disordered menstruation, the treatment should be directed according to the principles stated above (§ 68, 69.).

71. *B. With reference to the state of nervous susceptibility and tone.* — The increased susceptibility of the nervous system generally characteristic of hysteria is frequently associated with more or less debility, and increased irritability of the moving fibre, — or in other words, with mobility of the muscular system; and to this state, whatever may be other morbid conditions, should the treatment be in some measure directed. Yet the means which are the best calculated to correct this state are by no means obvious: for if it be associated with vascular turgescence of the uterine system, or with general plethora, antispasmodies, chalybeates, and other heating tonics may increase the complaint, although they will generally be of service in an opposite state of the vascular system. In general, therefore, the condition of the sensibility and irritability should be combated chiefly by frequent and *regular exercise* in the open air, by *early rising*, by sleeping in large airy apartments, by cold or *salt-water bathing* or the *shower bath*, by cold sponging the surface of the body, by a proper conduct and employment of the mind, and by a correct management of the passions.

72. Dr. Cullen very justly remarks, that *tonics* may be of service when the disease depends upon general debility; but as a plethoric state, especially of the uterus, is more or less joined with hysteria, the frequent or long continued use of them may do harm. They should be confined to cases of pure mobility, particularly with a periodical recurrence of the seizure; and then the selection of them ought to be determined by the peculiarities of the case. In many such, the preparations of *cinchona* or of *valerian*, with the nitrate of potash, or carbonate of soda; the sulphate of *quinine* or of *zinc*, with small doses of *camphor*; the infusion of *bark*, or of *roses*, with one of the *mineral acids*, and the tincture of the *sesquichloride of iron*, will be most serviceable. In some cases, the addition, to either of these medicines, of an *antispasmodic*, as of the compound spirit of *sulphuric æther*, the *tincture* of *valerian*, &c.; and of an *anodyne*, as henbane, hydrocyanic acid, &c., according to the other substances selected, will be further advantageous. When hysteria affects plethoric habits, and is connected with manifest signs of turgescence of the generative organs, *opium* is injurious. But, in other circumstances, it is often of service, particularly when conjoined with camphor, aromatics, or with some of the substances just named, but even then it should only be occasionally employed. When narcotics have not been previously resorted to, the preparations of *hop* will be found useful, if general plethora be not present.

73. *C. With reference to the states of the vascular system.* — The connection of hysteria with vascular plethora, general or local, is often obvious; and has been very judiciously viewed by Dr. Cullen. The usual practice of removing this state by *bloodletting*, he remarks, is often precarious; for sometimes, instead of preventing, it will indirectly induce or increase vascular fulness. Besides, if depletion be carried too far, the complaint may be thereby increased. "Venæsection therefore may either increase the plethora, or induce inanition; and it is only to be used in recent cases, and where there is manifestly a full habit." A *spare diet* and *regular exercise*, particularly in the open air and in the light of day, *early rising*, and *cooling aperients*, are the means upon which the chief reliance ought to be placed in removing this state, and especially as they tend also to strengthen the nervous system, and to prevent local turgescence and irritation. The frequent association also of dyspepsia, and of gastro-intestinal disorder with hysteria, renders this regimen still more necessary. When depletion, however, is indicated by the turgescence, or chronic inflammatory state of the uterine organs, or by impaired or obstructed menstruation, it should be practised in the manner already advised (§ 68.).

74. When the vascular system is deficient, rather than too full, of blood, and when this fluid seems thin or poor (the *Hysteria chlorotica* of Sauvages), then *tonics*, especially the *preparations of iron* and *chalybeate mineral springs*, will be most beneficial; but they should be aided by air and exercise, and the other means already advised for improving nervous energy (§ 71.). The sulphate of iron with the extract of hop, or with the compound galbanum, or with the compound aloetic

pill, according to the states of the bowels and of the catamenia; the compound mixture of iron, &c.; and a moderately nutritious or milk diet, will be eminently beneficial in these cases. If the patient complain of weaknes in the loins and limbs, a large *plaster* of the red oxide of iron, or the aromatic plaster, should be worn on the lumbar region, in addition to the employment of the other means already recommended.

75. *D. With reference to the state of the digestive organs.*—Irritation of the digestive mucous surface, in connection with hysteria (§ 52.), is often most successfully treated by a mild spare diet and moderate exercise in the open air. If the patient be plethoric, or complains of pain or soreness, or of tenderness in the epigastrium, abdomen, or hypogastrium, *local depletions*, particularly the application of leeches on the abdomen, and *cooling diaphoretics*, with external *derivatives*, will be appropriate, as respects both the digestive and the hysterical disorder. If the bowels be costive, the *cooling aperients* (F. 96. 790.), or the preparations of *rhubarb* with *ipecacuanha*, *calcined magnesia*, or *castor oil*, will be useful. If they be relaxed, the *hydrargyrum cum cretâ*, with *rhubarb* and *ipecacuanha*, — or this last with the *extract of hop*, or of *poppy*; and *refrigerants* conjoined with *demulcents*, will be serviceable. In cases of *hysterical colic*, and of irregularity of the bowels in hysterical persons, a frequent recourse to *enemata*, — to those consisting of cold or of emollient fluids, and sometimes of cooling aperients,—will generally prove of great benefit. When the catamenia are at the same time disordered, clysters containing the spirit of turpentine are frequently very useful. The state of the digestive organs often requires *tonics* and *stomachics*; but these remedies may prove too stimulating, unless they be given with *refrigerants* and *antacids*, as with the nitrate of potash, and the carbonate of soda. Aloetic and heating or acrid purgatives, particularly those which excite the rectum and large bowels, are sometimes injurious. The propriety of exhibiting them, even when hysteria is associated with scanty or obstructed catamenia, is occasionally even doubtful, particularly when general or local plethora, or excitement, is present, unless these have been removed by suitable depletions; and then the *compound decoction of aloes*, with a little of the solution of potash, may be preferred. When flatulence is distressing, as it often is, the treatment should altogether depend upon its connection with gastro-intestinal irritation, or with uterine excitement or turgescence. In the former case, the means just stated should be prescribed, aided by the application of a *large rubefacient plaster*, or the compound galbanum or pitch plaster, on the stomach or abdomen. Mint water with calcined magnesia, and an aromatic or carminative, or the infusion of *calumba*, or of *chyrita*, with the carbonate of soda and compound tincture of cardamoms, will generally also be serviceable.

76. iii. TREATMENT OF THE IRREGULAR AND COMPLICATED STATES. — The *intentions of cure* in these states of hysteria, are — 1st, *To remove existing disorder in the uterine and digestive organs, or in the cerebro-spinal centres*; — 2dly, *To allay the local affection, by means appropriate to its peculiar characters*;—and, 3dly, *To make a forcible impression, mentally and physically, on the nervous system*, so as to allay the primary nervous affection, and to break the chain of nervous sympathy. These intentions are severally more or less applicable to all the nervous states about to be noticed; but a great difference will be shown to exist in the modes or means of their fulfilment, and in the dependence to be placed upon them individually.

77. *A. The painful affections depending upon this complaint*, or arising from irritation or turgescence of the uterine organs, influencing sympathetically (§ 13.) related or distant parts, require means, in some cases at least, different from, or additional to, those already mentioned.—*a.* The treatment of *Hysterical headach* is fully stated in the article HEADACH (§ 40.).

78. *b. Pain in the left side of the thorax, simulating pleuritis*, or *pericarditis* (§ 15.), is difficult to remove, especially if there be tenderness in the dorsal portion of the spine, and disorder of the uterine functions. If the catamenia are scanty, and especially if there be more or less vascular plethora, cuppingon the loins or sacrum, or the repeated application of leeches to the loins, and cooling or mild purgatives, will be necessary. In other circumstances, and in such cases, after these means have been employed, the effects of *antispasmodics* and of *narcotics* may be tried, especially of camphor or ammonia, with valerian or assafœtida and henbane, &c. If the pain be attended by *palpitations of the heart*, &c., the decoction of senega may be prescribed with mint or orange-flower water, carbonate of soda, and tincture of henbane; — or camphor may be given in a mucilaginous mixture with hydrocyanic acid. Immediate relief is often obtained by applying on the pained part a piece of flannel wrung out of hot water, and sprinkled with spirit of turpentine, or with the following liniment: —

No. 261. ℞ Linimenti Camphoræ Comp., Linimenti Terebinthinæ Comp., āā ℥j.; Olei Cajuputi et Olei Limonis āā ʒj. M. Fiat Linimentum vel Embrocatio.

These embrocations should be covered by a dry cloth, or by wash-leather, to prevent evaporation, and be kept applied to the affected part until they occasion redness and burning heat of the integuments. I have seen the pain removed also by the inner bark of the mezereon, previously moistened and softened, and kept applied to the part until a superficial sore was produced. — If pain or tenderness in the spine be also complained of, the means about to be noticed (§ 85, 86.), may be prescribed.

79. *c. Hysterical pain in the regions of the stomach and spleen* (§ 17.) often resists medicine, and disappears spontaneously, especially after marriage, or from changes in the states of the uterine system. It is sometimes relieved by camphor conjoined with hydrocyanic acid or with the acetate of morphia, or by the other antispasmodics and anodynes mentioned above (§ 78.). The warm epithem and embrocation, just recommended, has, however, proved most successful in my practice. Large doses of the subcarbonate of soda, with a carminative mixture or spirit, and tincture of henbane or of opium, often afford relief. An enema, containing either the spirit of turpentine and castor oil, or assafœtida and confection of rue, generally proves very serviceable.

80. *d. When pain is severe in the region of the descending colon and left iliac region* (§ 18.), or in *other parts of the abdomen*, with flatulent distension, increased sensibility, and other symptoms

resembling *peritonitis* (§ 21.), the above treatment is more to be depended upon than any other. The warm epithem or embrocation should never be omitted. The enema just prescribed will seldom fail of emptying the large bowels, and of expelling the flatus which is a chief cause of the more painful symptoms. When the complaint assumes the form of *hysterical colic*, the bowels being costive, these means are usually eminently successful. They may require, however, to be repeated. If palpitations be present in these cases, they depend upon, or are aggravated by, the flatus which often rises up into the œsophagus, and, by distending a portion of this canal, embarrasses the auricles of the heart. Hence the benefit which results from the means which are most efficacious in expelling the flatus, particularly from those just named; and from calcined magnesia, prescribed with antispasmodics and carminatives, or warm purgative tinctures. — *For pain in the region of the liver* (§ 30.), the treatment here advised will be appropriate. In all these states of the complaint, the bowels should be kept moderately open by mild or stomachic purgatives.

81. *e. When pain is seated behind, or just above the pubis* (§ 20.), and particularly when it extends to the sacrum, to the os coccygis, or when it implicates the urinary bladder, or its functions, irritation, or vascular turgescence, or congestion of the uterus, may be inferred. Local depletions ought then to precede other means; and the mode, amount, or repetition, of depletion, should depend entirely on the habit of body of the patient, and the state of the catamenia. After those have been prescribed, the bowels must be evacuated by mild or stomachic purgatives, and the circulation equalised by cooling diaphoretics and anodynes. Camphor mixture, almond emulsion, solution of acetate of ammonia with nitrate of potash, spirits of nitric æther and tincture of henbane, are generally useful in these cases. But if the pain still continue, the external means above advised, and the enemata (§ 78, 79.), should be resorted to.

82. *f. Pain in one or both mammæ* (§ 29.) is sympathetic of irritation or turgescence of the uterus or the ovaria; but it is sometimes associated with tenderness of one or two of the dorsal vertebræ. It is often removed by the treatment now prescribed. If there be scanty menstruation, leeches may be applied to the mammæ; but the tops of the thighs, and hypogastrium, are preferable situations. I have found cooling diaphoretics with narcotics, as the solution of the acetate of ammonia, and camphor julep, with the acetate of morphia and an aromatic spirit, very serviceable in this state of disorder. In a case of this kind, where there were remarkable tenderness and hardness of the left mamma, evidently depending upon uterine irritation and turgescence, and for which I was consulted by another practitioner, complete recovery followed a short course of the solution of the iodide of potassium in camphor mixture, to which the solution of potash and henbane were added. If tenderness exist in any of the dorsal vertebræ, the treatment advised for this complication (§ 85.) should also be pursued.

83. *g.* In the *more acutely painful or neuralgic affections* connected with uterine disorder, the effect of a plaster with the extract of belladonna and camphor may be tried. But when they are associated, as sometimes observed, with pain or tenderness in some portion of the spine, then the other local means about to be noticed may be also employed. I have seen the most marked benefit result, in these more acute cases, from half an ounce each of spirits of turpentine and castor oil, taken on the surface of milk, and repeated once or twice after the intervals of a day or two; or from a full dose of the former medicine, followed by the enema already mentioned (§ 79.), or by any suitable purgative. Repeated doses of turpentine, until either the kidneys are affected, or the bowels are entirely evacuated, and enemata containing a considerable quantity of this substance, will be found the most efficacious, when painful affections, connected with hysteria, are seated in, or extend to, the lower extremities.

84. *h. Pain in the region of the kidneys, and in the course of the ureters* (§ 22.), is evidently an extension of irritation from the uterus to these organs by direct sympathy, — a considerable portion of the nerves of the generative and urinary organs belonging to the same ganglia. The treatment should, therefore, be chiefly directed to the state of the uterine system. Local depletions will sometimes be requisite, especially if there are general or local plethora, and scanty menstruation. The fixed alkalies or the alkaline subcarbonates, with anodynes and the spirits of nitric æther or the compound spirits of juniper, will occasionally be of service, especially when the urine deposits a sediment of uric acid in the form of sand. When the urine is higher coloured, or deposits a pink or amorphous sediment, consisting chiefly of the lithate of ammonia, the infusion or decoction of cinchona with hydrochloric acid, or the balsams taken in the form of pills with magnesia, will be found beneficial. The digestive functions should receive due attention. A rubefacient, stimulating, or roborant plaster applied on the loins, as the aromatic, cummin, pitch, or ammoniacum plaster, will often also afford some relief.

85. *i. Pain in the spine* (§ 23.) is rather a complication, than a form, of hysteria; and is not to be viewed as altogether, or always, depending upon inflammatory action or irritation; but rather upon excited sensibility. There is no doubt that vascular excitement or congestion often exists in these cases, especially where there is much tenderness or prominence of one, two, or more of the spinal processes, or puffiness around them. In these cases, especially, there is more or less continued disorder of the uterine, or of the digestive, or of the respiratory functions, or even of all of these, according to the seat and extent of the spinal affection; and occasionally the cerebral circulation becomes also deranged. To this affection, DARWELL, TEALE, TATE, BROWN, and GRIFFIN have directed particular attention, under the name of *Spinal Irritation*, or, more properly, irritation of the spine, and have recommended for it local depletions and external irritants, &c. But whoever confides in these alone, or even principally, will find himself disappointed in many, if not in the majority of cases. They often, however, are important parts of the treatment, especially if plethora, general or local, or scanty menstruation, exists. In cases of this description,

the digestive functions should receive strict attention, the bowels being kept regularly open. In the majority, and particularly if there is debility or deficiency of blood, or too frequent or too copious menstruation, the sulphate of quinine, with camphor and extract of hop, or extract of hyoscyamus; the preparations of cinchona, with the alkaline subcarbonates, or with the mineral acids, according to circumstances; and the preparations of iron; will prove of great service, if appropriately administered. In some instances of the association of hysterical affection with tenderness of the spine, and with neuralgic pains in the corresponding nerves, I have found, after local depletions and alvine evacuations, pills containing full doses of the sulphate of quinine and sulphate of iron, with camphor and extract of hyoscyamus, very beneficial, and have added the purified extract of aloes to them with advantage, when the bowels were costive, or the catamenia deficient. Where the powers of the constitution are not impaired, or where there is excited action, an occasional recourse to the draught with spirits of turpentine and castor oil, or to the enema containing the same substances, will be of essential service.

86. *External means* of various kinds have been applied to the spine in these cases, often without benefit, sometimes with detriment, particularly when the increased sensibility depended upon sympathy with other parts, and upon great nervous debility. When there is sufficient evidence to infer that inflammatory irritation and turgescence have been excited in the membranes or investing structures of the spinal cord, then certain of these applications, as leeches, scarification and cupping, the tartarised antimonial ointment, or issues, will be more or less beneficial; but in other circumstances they will be of no service. The relief which has followed the application of blisters, or of rubefacient and stimulating plasters, is no proof that the morbid sensibility of the spine depended in these instances upon inflammatory excitement or vascular turgescence; for, if these morbid states had existed in any degree of sthenic activity, these applications were more likely to have aggravated, than to have removed, them. Where they have actually given relief, there is reason to infer that the morbid condition was one of deficient vascular and nervous energy, rather than the reverse; and one for which general restoratives or tonics, as well as local excitants, were required. Much attention to the states of the various functions, particularly of those of the abdominal and pelvic viscera, and great discrimination, are necessary in these cases, to determine aright as to the local means appropriate to the various conditions of this class of affections. There are some applications which will not be injurious under any circumstance, but will be serviceable in many. The chief of these are the warm terebinthinate epithem and embrocation already noticed (§ 78.), applied over that part of the spine, chiefly, where pain is felt. Plasters, also, consisting chiefly of ammoniacum, compound pitch, or of red oxide of iron, &c., will subsequently prove useful. Where signs of inflammatory action of the ligamentous or other structures of the spine are present, the above liniment, epithem, or embrocation, applied to the affected part; and setons, issues, or open blisters, some distance below it, so as to produce a derivation from the seat of morbid action; will frequently afford great relief.

87. *k. Pain in the sacrum and os coccygis* is generally not to be imputed to the same morbid states, as that referred to the spine. It frequently depends upon the condition of the uterus, particularly about the *os* and *cervix uteri*, and requires the same treatment as that advised for pain behind or above the pubis (§ 81.). Whether proceeding from this source, or from disorder near the origins of the nerves, or from disease of the structures of the spine, or of adjoining parts, the means just recommended, constitutional as well as local, will be useful when judiciously employed.

88. *l. Hysterical affections of the hip or other joints* (§ 26.) are very difficult to manage, and require, for their removal, not merely an improvement of the general health, but also strong impressions upon the mind and nervous system. The *intentions of cure* above stated (§ 76.), should be fully followed out, and the particular means already described fairly tried. The medicines which I have found the most successful are — the *spirits of turpentine* *, prescribed in various modes, internally and externally, and administered in enemata; the *preparations of iodine*, alone, or with *narcotics*; and *camphor*. These, however, should be associated with suitable adjuvants; amongst which, the several *narcotics* and *antispasmodics* are the most important. The warm or vapour bath, simple or variously medicated; mental excitement, and exercise taken regularly and energetically; and employment of the mind; are also important aids in the treatment. The affections of the joints are sometimes accompanied, or even alternated, with severe nervous pains in the extremities, and occasionally with tenderness in some portion of the spine. In such cases, the treatment hardly requires any material alteration. In those which have come under my care, I have very frequently prescribed the spirit of turpentine, as already stated (§ 83.), and often repeatedly in enemata; and, after two or three doses of it, I have commenced with the preparations of iodine, conjoined with henbane, opium, or belladonna. Whilst the iodine has been given, the turpentine has been administered in enemata, from time to time; and the embrocation or liniment above described (§ 78.), assiduously employed. In recent cases, particularly when the knee-joint was affected, this treatment has removed the disorder in a few days. In the case of a lady, whom I saw with Mr. FAXON, the complaint in this joint was almost instantly removed by the warm turpentine epithem applied around the knee. Various other medicines may be tried, and, indeed, require to be tried, before some of the foregoing will be submitted to by the patient. Most of the cases which I have seen, have been very obstinate, and have been treated by the more usual remedies, as the mineral sulphates, the preparations of iron, the sulphate of quinine, narcotics, &c., before I saw them. Sir B. BRODIE mentions favourably a

---

* The spirit of turpentine was first recommended by the author for these states of hysteria, and for neuralgic and similar affections. It has recently been advised for the same complaints by some French physicians. The originality of the practice may be known, by referring to *A Memoir on the Employment of Terebinthinous Remedies in Disease*, by JAMES COPLAND, M.D. &c., published in the *Lond. Med. and Physical Journal*, for July and August, 1821, p. 107—193.

long continued course of the sulphate of copper in small doses. The external application of the vegetable alkaloids, and of their salts, particularly veratria, aconitina, &c., in ointments or liniments, has recently been recommended for cases of this description, and particularly for those attended by neuralgic pains, in much stronger terms than the real advantage derived from them warranted. I have prescribed these preparations in several instances of this kind, and have had the prescriptions prepared by the very best chemists, but permanent advantage was seldom derived from them.

89. Local hysterical pains will sometimes be relieved by friction with a stimulating liniment containing some narcotic (F. 297. et No. 261.) Sir B. Brodie recommends a lotion consisting of equal parts of spirit of rosemary and camphor mixture to be applied tepid to the affected part. The simple exposure of the part to the vapour of hot water — the heat and vapour being confined by oil-skin, or by any other means — will often be useful. The vapour bath, employed thus locally, will be still more serviceable when the affected limb is cold, or is alternately hot and cold. It has been recently prescribed by Dr. J. Wilson in these and similar affections. (*Pract. Treat. on the Curative Effects of Simple and Med. Vapour applied locally, &c.* 8vo. Lond. 1837.) — Sir B. Brodie states, that he has found the hysterical painful affections characterised by alternations of heat and cold, much relieved by the following plan: — "During the hot fit, let a compress be applied wet with a cold spirituous lotion; and when the heat has subsided, let a thick woollen stocking be drawn over it, and then an oiled silk covering over the stocking, so as to confine the heat and perspiration. When the cold fit has subsided, the oiled silk covering may be removed. This treatment, however, should be combined with the exhibition of the sulphate of quinine." I have found the quinine more beneficial when given with camphor in these cases. The oxides or carbonates of iron may also be tried in electuaries; and conjoined with the confection of senna or of scammony, when the bowels are costive.

90. *B. When hysteria assumes anomalous spasmodic forms, or stimulates other spasmodic affections* (§ 31.), the same principles of treatment as have been already explained should be adopted, according to the states of general or local vascular plethora, and of uterine function, and to the symptoms referrible to the spine. There are few cases of this kind in which the spirits of turpentine, judiciously prescribed, or administered in enemata, will not prove of essential benefit; and some will require, in addition, the warm epithem, liniment, or embrocation, already described (§ 78.). But these can often be resorted to only at considerable intervals. The tonics, antispasmodics, and anodynes, — the general plan of treatment recommended, — must be duly exhibited; and if evacuations be necessary, they should be resorted to as above directed. In most respects, these affections require nearly the same *indications of cure*, and the *same means* to fulfil these indications, as have been directed for the more painful complaints just passed under review, and particularly for those seated in the joints and extremities.

91. For *hysterical cough* or *asthma*, antispasmodics with anodynes or narcotics are very useful. The preparations of valerian with ammonia or camphor, and henbane; a weak decoction of senega with emollients and hydrocyanic acid; small doses of ammoniacum, assafœtida, or of squills, with demulcents; the alkaline subcarbonates and extract of poppy, &c.; will severally be found of service. The treatment, however, must be modified, as previously advised, according to the states of the constitution and habit of body, of the catamenia, and of the temperature of the surface. The *external means* described above (§ 86.), will very materially assist the internal remedies; and sometimes the warm bath will be useful. — In *hysterical hiccup*, camphor and other antispasmodics, with anodynes, and the means just noticed, cold fluids, and cold enemata, will be found advantageous. (See also the *Treatment* advised for Convulsions, and for Chorea and its related Affections.)

92. C. *The comatose, cataleptic, or soporific states of hysteria* (§ 33.) require but slight modifications of either the indications or means insisted upon above. During these states, the remedies advised for the paroxysm may be employed, appropriately to the local or general states of the circulation; and the most important of these are cold affusions or cold lotions on the head; and, in some instances, enemata of cold water, or containing the spirit of turpentine, or assafœtida, or camphor. Subsequently the treatment should be directed according to the state of the cerebral circulation. In most cases of this kind, the disorder of the uterus has excited, or otherwise deranged, the circulation in the brain; but generally in such a manner as to be relieved by the shower bath, or by frequently sponging the head with cold fluids. Due attention to the states of the bowels and of the catamenia, and the other means advised for Catalepsy and Cataleptic Ecstasy (§ 18.), are necessary for cases of this kind. When hysteria assumes the form of *syncope* or *leipothymia*, sprinkling the face with cold water; the *cold douche*, or affusion on the head; volatile or empyreumatic vapours, held at some distance from the nostrils; bathing the face and neck with aromatic waters or spirits; pure air, &c.; are the chief means of restoration; after which the treatment must be conducted as above.

93. *D. Paralytic affections and aphonia* (§ 35.) hardly require any notice as respects the treatment, as the *indications* and *means* of cure already prescribed, are equally appropriate for them. After the bowels have been freely evacuated, and local irritations or congestions removed, a resolute exertion of volition, exercise in the open air, and mental and bodily employment, as far as they can be pursued, are especially beneficial in them, particularly when aided by a judicious administration of tonics or antispasmodics; by suitable diet and regimen (§ 100. *et seq.*); and by recourse to external remedies—particularly to frictions of the surface with stimulating and rubefacient liniments, to warm or medicated baths, &c.—When the paralytic state is manifested chiefly in the alimentary canal or urinary bladder, enemata containing the spirit of turpentine, or the warm terebinthinate epithem, or embrocation, applied over the abdomen, will be found almost immediately efficacious.

94. *E. Hysterical disorders of the mental faculties* consist not merely of the states already men-

tioned (§ 38.), but of others, of a less decided, but not less morbid, kind. Hysterical females are not merely capricious or whimsical; but they often become enthusiastic for a time, in the pursuit of an object, or in cherishing an emotion by which they have been excited. In many such cases, the nervous excitement and vascular turgescence of the uterine organs determine the character of the mental disorder; elevating certain of the moral sentiments, or of the intellectual manifestations, to a state of extravagance, passing, in some instances, into delusion or monomania. Many cases of puerperal mania are merely extremes of the hysterical disorder of the moral and intellectual powers or states of the mind. All these more extreme forms of mental affection are observed only where, in connection with much local or uterine irritation, there is great deficiency of nervous energy generally, and of mental power in particular; or where, with such deficiency, there has been either much injudicious culture, or perversion, or improper excitement, of the imagination.

95. Females sometimes become passionately attached to an object; and this passion may advance even to nymphomania or monomania. The same person, on experiencing a disappointment in her affection, or if she be placed in circumstances entirely preventing the enjoyment of her passion, often becomes enthusiastically religious, especially if powerfully excited by popular preachers. After field preachings, or other ministrations of an exciting kind, the most hysterical females, especially those who have experienced the fully developed fits on these occasions, have become, at least for a time, the most religious. In this, however, there is little to regret: there is no harm, and generally much good, from this direction of the feelings; unless, indeed, advantage be taken of this excitement by certain Tartuffes, especially at love-feasts, &c., — a circumstance by no means rare.

96. The hypochondriacal feelings, the desire to deceive, or to simulate various diseases, or the delusions, which sometimes possess the minds of hysterical females, may be classed with the foregoing, as requiring a similar plan of treatment. In all of them, the *intentions of cure* are — to remove irritation or vascular turgescence of the uterine organs; to improve the general health; to strengthen the nervous system; to calm the imagination; and to guide the moral impulses of the patient. The means by which the physical portion of these indications are to be fulfilled, have been sufficiently explained. The most efficient, however, of these means are not likely to be adopted by the patient, if she is entirely uncontrolled by friends. Few will resort daily to the shower bath, or even occasionally to terebinthinate enemata, or submit to a course of tonics, or to a suitable regimen, &c., whilst she believes her health but little affected. Even when the hysterical disorder is of a very painful kind, the variability or capricious state of her mind leads her to run from one physician to another, before opportunity of administering aid is afforded to any. At last, the most notorious charlatans, particularly those who either excite the body through the mind, or the mind through the body, — the animal magnetisers, the Homœopathists, the St. John Longs of rubbing celebrity, and the Campbells of celestial-bed notoriety, — fix her attention. At such medical bagnios there is something promising gratification as well as excitement, and at such places hysterical as well as hypochondriacal patients "most do congregate."

97. iv. OF THE PROPHYLACTIC TREATMENT OF HYSTERIA. — *a. The avoidance of the occasional causes* is the chief part of this treatment; and this is very difficult. The moral emotions and desires constitute the principal of these causes, and the prevention of them is not in the power of the physician; and, considering the general frailty of our nature, rarely in the power of the patient. — A physician, sufficiently acquainted with human nature, and with human life and society, will frequently discover the connection of the complaint with the feelings, and be able to give useful hints to the patient or her friends, as to the moral as well as to the medical management of the complaint. But his proper business is to correct the predisposing or constitutional cause, and to enable the patient to resist the exciting causes. An indolent, a luxurious, and an unoccupied life, leads to late hours in bed, to an excited state of the imagination, to susceptibility of the nervous system, to irritation and turgescence of the generative organs, and to general or local plethora. It cannot be sanguinely hoped, that females will relinquish ease, luxury, and enjoyment, from the dread of a distant and contingent ill. Most physicians of experience must have often observed the influence of these causes on the health, and have met with instances of females, who, when in ease and luxury, were subject to hysteria, having become entirely free from it, when reverses of fortune obliged them to employ both mind and body.

98. *b.* Much depends upon the *moral* and *physical* education of females about the period of puberty, in preventing hysteria. If more time were devoted to air and exercise, and less to mere accomplishments — if less strenuous efforts were made to cram much ill-assorted knowledge into the mind, in a very limited period — than usually is the case in the present day, an improved state of nervous energy, and of constitution generally, would result. There would consequently arise a race of females, possessed of stronger minds, and better able to make good wives and healthy mothers, than those too frequently met with in the easier ranks of life.—Of all the physical influences, by which the human constitution is permanently impressed in early age, there are none so powerful as *light*, *air*, and *exercise*. Females, while the frame is being developed, should strictly observe early hours, so that the *period of repose* should never be prolonged much after the dawn of morning. The propriety of *sleeping* in a large, well-ventilated room, cannot be disputed. It will be prudent, where more than one must sleep in the same apartment, to have separate beds, each no larger than is necessary for one person; and if the room is sufficiently large and airy, three, but no more, should sleep in it, preferably to two. When very early rising is enforced, the kind of bed, on which growing females should sleep, is not very important, although a hair mattress is perhaps the best; but the bed-clothing should be light, and the sitting, as well as the sleeping, apartments ought to be moderately cool and airy.

99. The kind of exercise which is most serviceable, is that taken in the open air and in the light

of day, and which brings into action the voluntary muscles generally, especially those of the lower extremities. It should preferably be on foot, and be regular, daily, and neither too little nor excessive. SYDENHAM, FULLER, MANDEVILLE, and MANNING advise riding on horseback, as affording the briskest motion, and occasioning the least fatigue. It ought always, however, to be used when the stomach is most empty; for, after a full meal, it retards digestion, rendering it uneasy and flatulent. It is most serviceable when hysteria is associated with retention of the menses, and a chlorotic state of the system, or when there is torpid action or obstruction of the digestive and abdominal viscera. In cases of this description, the advice given by MANDEVILLE will be found of great benefit. This is, to rise before six; to have half an hour's exercise in a swinging chair, flying horse, or the common swinging rope, and then breakfast; some time afterwards to get on horseback, for at least two hours, either galloping or trotting, as much as her strength will permit her; and, immediately after this, to be undressed, and assiduously chafed or dry-rubbed for a considerable time, till her skin looks red, and her flesh glows all over. MANNING observes, that frictions are useful, not only in the cure of the paroxysm, but also as a prophylactic. He directs them to be used on the extremities and trunk of the body, and especially on the abdomen when the digestive organs are weak. If hysteria be attended with the anomalous symptoms already noticed, or assume an irregular form, friction applied daily and assiduously along the spine, will be of great service. Sailing has been recommended by Dr. GILCHRIST, in the treatment of hysterical and other nervous complaints; and in certain circumstances it will be found useful.

100. *c.* *Cold bathing*, particularly salt-water bathing and the shower bath, will generally be serviceable at this period of life, if females have no particular dread of either, and if the surface of the body be afterwards well rubbed, and smart exercise immediately taken. For delicate constitutions, with a predisposition to the disorder, it will be preferable to commence with a warm salt-water bath, or with a tepid shower bath, the temperature being gradually lowered to the usual grade. Sponging the surface of the body also, every morning, with salt and water, or with water containing some vinegar or a little of the nitro-muriatic acid, the temperature being at first tepid, but gradually reduced to the usual mean of cold, will generally prove most beneficial, not only in preventing the complaint, but also in removing it.

101. *d.* Various *mineral waters* frequently prove of great advantage in the preventive, as well as in the curative, treatment of hysteria. There is no doubt of the *Bath* waters being often beneficial in this complaint, although fashion has brought them into disuse, by bringing others into more general notice than they deserve. In females of a delicate constitution, with a languid state of the circulation, and want of tone of the nervous and muscular tissues, these waters, with proper management, will generally be most useful. In a similar state of system, the mineral waters of *Vichy*, *Barèges*, *Marianbad*, *Eger*, *Carlsbad*, *Pyrmont*, *Spa*, *Hartfell*, and *Tunbridge*, will also be of great service, if employed appropriately to the pathological peculiarities of the case. The stronger chalybeates, however, should not be prescribed when the complaint is connected with general plethora, or where there is very marked vascular turgescence, or excited action of the generative organs. Where these waters are indicated, as well as in more doubtful cases, the springs of *Ems*, of *Bath*, and of *Seltzer*, will often be very beneficial. Seltzer water with warm milk may be used as the common beverage in most cases. As most of these waters may be procured in London and Brighton, there can seldom exist much difficulty in trying them, without leaving this country, or even the patient's home. The warm mineral waters can, however, be used only in *Brighton*, where they are prepared in a way not much inferior to their natural state. — In connection with the use of suitable mineral waters, *change of air* will be most beneficially prescribed. Indeed, much of the benefit attributed to the former actually proceeds from the latter; and in all cases where benefit is derived, both means are concerned in producing it.

102. *e.* The *diet* of hysterical females, as well as the medicines prescribed, should have strict reference to the states of the vascular system and of the uterine organs. In general, a milk diet, as advised by SYDENHAM, is very serviceable, particularly where debility is present; but much animal food is hurtful, especially where there is a tendency to plethora. A fish diet, and the use of shell-fish, are not less injurious, as favouring uterine turgescence, although much less productive of vascular fulness. A spare and cooling diet, consisting chiefly of farinaceous substances, is the most generally appropriate; but a somewhat liberal use of animal food is occasionally requisite. Slops, as weak tea, should be avoided. Boiled milk and bread should be preferred to either tea, chocolate, or coffee. The last is generally too heating, and ought not to be allowed, when the symptoms of uterine turgescence or irritation become very prominent.

103. *f.* Patients subject to hysteria should avoid warm apartments, and crowded rooms or assemblies. The extremes of *temperature* are often injurious to them. They should preserve their extremities warm, and be careful not to confine any part of the body, and particularly the waist, by too strait clothes or stays. — Mental and physical *occupations* are amongst the most beneficial means of treatment in this complaint; and advice respecting them should never be overlooked by the physician. The nature or kind of employment must entirely depend upon the circumstances and condition of the patient. The reading of exciting novels and of loose romances, and even music, are mere dissipations of time. The former ought not to be permitted by those who have the power of preventing it: and the latter should be subjected to a judicious control, and cultivated truly as an accomplishment, and as a relaxation from severer, and more rational, and more useful occupations.

104. As to advising marriage for young hysterical females, this, perhaps, may be as well let alone, although I do not altogether agree with MANDEVILLE, as to the risk of their children inheriting the complaint. He remarks, " in the first place, it may fail, and then there are two people made unhappy instead of one; secondly, it may but half cure the female, who may have half a

dozen children that shall inherit it. A physician has a public trust reposed in him: his prescriptions, by assisting some, ought never to prejudice others; besides, a young lady may not marry so well whilst she labours under this infirmity, as if she was in perfect health. Therefore, let her either be first cured, and then marry without being injurious to herself, her husband, or her posterity; or else remain single, with this comfort, at least, in her affliction,—that she is not liable to entail it upon others, who should be no less dear to her than herself." A principal reason for hysterical mothers having children that are hysterical and nervous, is, that they are generally bad nurses,—their milk being either deficient, or innutritious: when their infants are suckled by strong and healthy nurses, no such hereditary influence is usually observed. Nothing is of greater advantage in hysterical disorders, than mental tranquillity and cheerfulness. Fear, grief, and anxiety ought to be avoided, and the mind should be agreeably entertained and interested by useful employment.

CLASSIF. — 3. *Class*, Cachetic Diseases; 3. *Order*, Cutaneous Diseases (*Cullen*). 1. *Class*, Diseases of Digestive Function; 2. *Order*, Affecting the Viscera (*Good*). IV. CLASS, I. ORDER (*Author*, in *Preface*).

1. DEFIN. — *Yellowness of the eyes and skin, sometimes passing to a yellowish-green hue, or even to a greenish brown; the urine being of a saffron or deep colour, the stools generally pale, and the course of the bile obstructed.*

2. There are few diseases, the nature and morbid relations of which have occasioned greater diversity of opinions than jaundice. By some it has been viewed as a symptom of derangement, or of organic lesion, of the biliary apparatus, more immediately dependent upon obstructed discharge, and upon absorption, of bile. Others have considered it as independent of absorption of this secretion, and as the result of a morbid state of the capillary circulation. These, as well as other opinions, will be more fully noticed in the sequel; and I shall then show that it cannot be considered merely as a symptom of the morbid states of the biliary apparatus, to which it has commonly been attributed, although very often connected with, and sometimes originating in, these states. It occasionally appears in the course of bilious fevers, when there is no obstruction to the evacuation of bile. But the yellowness observed in the last stage of yellow and malignant fevers is not a symptomatic jaundice, the change of colour depending, in these maladies, upon the morbid state of the blood, and upon the change in the capillary vessels and circulation, independently of biliary bstruction.

3. Jaundice is generally *sporadic*; but, according to MONRO, ALIBERT, and others, it has assumed, on rare occasions, an *epidemic character*, particularly at the terminations of campaigns, and after, or during, very wet summers and autumns. It was thus said to have been epidemic in Cronstadt, in 1784 and 1785; and at Geneva, in 1814.—It is *endemic* in some places, particularly those in which, with a high range of temperature, the sources of malaria abound (see ENDEMIC AND EPIDEMIC INFLUENCES); but it is generally owing to the prevalence of biliary diseases and periodic fevers in these localities, that jaundice is also endemic.

4. I. SYMPTOMS.—*A. Precursory.*—Jaundice generally approaches with languor, depression of spirits, slight chills or rigors, anorexia; with uneasiness, tension, or weight at the præcordia; with flatulence, sour eructations, sometimes nausea or vomiting, or other disorders of the stomach; or with colicky pains, disturbed or irregular bowels, and headach. The stools are hard, ash-coloured, clayey, or whitish, indicating an absence of bile; and sometimes relaxed, although the evacuations are pale or whitish. In rarer cases, the biliary secretion is apparently more than usually profuse. The stools are commonly devoid of their usual odour, and are more or less offensive. There is an unpleasant taste in the mouth, with some thirst. The tongue is loaded at its base. The skin is dry, and an itching or stinging is often felt on the surface. These symptoms are usually of short duration, and the affection manifests itself with much celerity.

5. *B.* The *yellow tinge* generally begins in the eyes, and extends to the temples, brows, and face; and thence to the neck, chest, and whole surface of the body. The colour is deepest in the wrinkles and folds of the skin, and in the lines of the face and hands. Sometimes it is distributed in deeper patches in one place than in another. It commences in the superior parts of the body, appears latest on the inferior extremities, and departs first from the parts where it commenced. The colour varies from a light yellow or lemon-colour, to a greenish brown; the intermediate shades of pale yellow, deep yellow, and yellowish green, being most common. With dryness of skin there is generally increased heat, particularly on the hands and feet. The itching and stinging are often also augmented, especially towards the night, and are most troublesome about the nostrils. In the more advanced stages, this symptom is diminished. The perspiration often then becomes free, particularly if the disease be attended by fever; and in some cases so abundant as to wet the linen, and to tinge it of a deep yellow. Sometimes a desquamation of the cuticle, or a psoriform eruption, follows these symptoms.

6. The bowels are frequently costive, and the fæces clayey, pale, and scanty; but in some cases they are loose, and have a peculiar fœtor. The urine is commonly high-coloured; yellowish and limpid at the commencement, afterwards deep saffron-coloured or reddish, frothy, and thick. Sometimes it is nearly black, depositing a brick-coloured sediment; at other times a dark deposit. As the disease subsides, the urine resumes its clear and limpid appearance, unless dropsy supervene. The patient generally complains of a severe, heavy, or lancinating headach, with a sense of heat, particularly at the forehead; and he often falls into a state of despondency or melancholy, or becomes morose. There is sometimes lethargy, and frequently watchfulness. The tongue and palate are coated with a yellowish sordes, and a bitter taste is felt in the mouth. The appetite is extremely irregular; sometimes being entirely lost, at other times ravenous. Thirst is usually present. Pain, weight, or a dragging sensation, and tenderness, are often felt at the epigastrium; frequently with flatulence, acrid eructations, nausea, difficult or painful digestion, and vomiting of a bitter, acrid, and sometimes dark, fluid. In some cases, acute pain runs in the course of the common duct, and increases as it reaches the epigastrium, with more or less uneasiness in the region of the liver, and top of the right shoulder, or beneath the right scapula, or between the shoulders. Violent pain is occasionally felt in the stomach, with short fits of colic. The respiration is readily accelerated, especially upon exertion; and there are sometimes paroxysms of cough. The pulse varies exceedingly. At the commencement, it is often hard and strong, but it is also frequently feeble, particularly as the disease advances. When severe paroxysms of pain are complained of, the pulse generally becomes frequent, hard, or full; but it is occasionally much slower than natural. Hæmorrhoids sometimes occur during

the disease; and they have often, after having discharged freely, proved a salutary crisis. Epistaxis has also been followed by a favourable result; but less frequently than the former evacuation.

7. Some *anomalous* appearances have been remarked during jaundice, which are deserving of notice, from the light they may throw on its pathology. The most important of these are — 1st. The suddenness of the attack — the almost instantaneous occurrence of it after violent affections of the mind. — 2d. Its restriction to particular parts of the body. BEHRENS, VALSALVA, ETTMÜLLER, and others, have observed it confined to the palsied side, in cases of hemiplegia. Dr. CHAPMAN has seen it limited to the face. A similar case has occurred to myself: and instances of its appearance only in the eyes are not uncommon. Allied to these states is the varying deepness of colour in different parts of the body. The deep greenish brown, verging to black, of the skin, commonly called green or black jaundice, described by Dr. Baillie, has been observed in one part of the body, whilst the usual yellow tinge has existed in others. LANZONI met with a case, wherein the throat and face were green, the right side of the body a greenish black, and the left yellow.— 3d. The yellow tinge, which objects occasionally exhibit to the patient during this disease, has been a matter of dispute; but it has been noticed, and believed in, by the majority of ancient authors; and was first disputed by MERCURIALIS, and afterwards by HALLER, HEBERDEN, CHAPMAN, and a few others. I believe it to be of rare occurrence, but to undoubtedly occur, when the cornea, or humours of the eye, participate in the yellow tinge, with the other parts of the body.

8. *C.* DURATION. — Jaundice may disappear, or terminate fatally, in a short time; or it may continue for many months. When it proceeds from moral or mental causes, it is generally of much shorter duration, than when it depends upon visceral disease. In the latter case, it may endure even for years. — But instances sometimes occur of its rapidly fatal termination, when proceeding from acute visceral inflammation, particularly from inflammation of the substance of the liver, and when accompanied by depressed vital power, much fever, and a very frequent pulse. I have seen death occur as early as the fourth day in such circumstances. The darker forms generally proceed more rapidly, especially to an unfavourable issue, than the lighter shades of the complaint. But the duration of it entirely depends upon the constitutional powers of the patient, and the pathological conditions which occasion it.

9. *D.* TERMINATIONS. — Jaundice, like most other diseases, terminates in three ways. — 1st. In a return to health; — 2d. In some other malady; — and 3d. In death. — *a.* Restoration to the healthy state generally takes place without any apparent crisis, although a critical evacuation is sometimes observed. As soon as biliary obstruction is removed, the stools become darker; the urine paler, and the discoloration of the skin begins to disappear, the parts first changed being the first to regain their healthy hue. The *critical evacuations,* are *bilious diarrhœa,* very abundant *perspirations, hæmorrhoids,* and *menorrhagia.* In a case which I lately attended, the jaundice rapidly disappeared after the discharge of a blackish inspissated bile, which had evidently accumulated in the hepatic ducts and gall bladder for a long time. The quantity of this pitchy or tar-like matter which was evacuated, was surprising, furnishing a striking instance of the black bile or melaina of the ancients.

10. *b.* In other cases, the disease either acquires increased intensity, or assumes a modified character; — one of the varieties hereafter to be particularized occasionally changes into another. — In some instances, additional disorder is superadded, a severe or dangerous *complication* thus resulting; and in others, the jaundice disappears, but is replaced by another malady. Lethargy, coma, apoplexy, epilepsy, phrenitis, diarrhœa, cutaneous eruptions, inflammation and abscess of the liver, disease of the spleen or of the pancreas, dropsy, rheumatic attacks, &c., may thus supervene — the jaundice still persisting; — and ascites, anasarca, dysenteric attacks, abscess of the liver, and chronic enlargement of the spleen, may follow upon its disappearance. Jaundice is often, also, a symptom of inflammation and abscess of the liver; although these latter are sometimes consequences of the pathological state upon which this affection depends, particularly when they appear subsequently to it. But it is much more frequently a symptom merely; and is oftener consequent on, than antecedent to, or coetaneous with, inflammation or abscess of this organ. Indeed, chronic inflammatory action, or active congestion of the substance of the liver, giving rise to jaundice, is more common, and antiphlogistic means are much more frequently required for the removal of it, than is supposed.

11. *c.* The termination in death may be preceded by the morbid states now enumerated, particularly when they assume their worst forms; — or it may be ushered in by increasing and urgent depression; by sinking of vital power; by great despondency; by ascites or œdema of the lower extremities, or both; or by hydrothorax; by great emaciation, hectic fever, and total loss of the digestive and assimilating functions, and by irritability of the stomach. In some cases, it has given rise to lethargy, coma, apoplexy, palsy, convulsions, or delirium, previously to a fatal issue. — It occasionaly happens, as observed by Drs. CHEYNE and MARSH, that persons labouring under jaundice, whose nervous system has been previously injured, or greatly exhausted, are suddenly seized with cerebral symptoms, and die either phrenitic, or apoplectic, or in convulsions. But death by the sudden occurrence of coma, which becomes more and more profound, is the most common. Delirium also often precedes a fatal termination.

12. *E.* FORMS and STATES. — Jaundice may be considered as *idiopathic,* when it supervenes suddenly upon violent affections of the mind. It is *symptomatic,* — its common form, — when it proceeds from diseases of the liver and biliary apparatus, or from obstruction of the common bile duct, or from lesions of adjoining parts, &c. To these some authors have added a third form, which they have termed *critical.* GRIMAUD states, that it has occurred as a crisis in some fevers: and BIANCHI makes a similar remark, — at the same time stating, that when jaundice is critical, the

urine is almost or altogether natural; whilst in its symptomatic form it is generally of a deep yellow, and otherwise much changed.

13. Jaundice may present various *degrees of severity*. It may be accompanied with great febrile excitement, and thus assume an *acute form*, and quickly arrive at its termination. When this is the case, it is generally accompanied with active hepatic, or other visceral disease, and often passes into a very deep or greenish hue. I was recently called to a gentleman, aged about fifty, of a strumous diathesis, who had begun to ail the previous day. I found him slightly jaundiced, remarkably depressed in spirits, with a sensation of sinking at the epigastrium, the pulse being upwards of 120, and soft. The evacuations were at first clay-coloured and costive, but they soon became copious, black, and tar-like. Delirium appeared on the following day: spontaneous hæmorrhage from the bowels occurred, followed by coma, relaxation of the sphincters, and death on the fourth day. The jaundice progressively increased, and, on the third day, the surface had become a greenish brown. The friends would not allow the body to be inspected.

14. Jaundice may also proceed in an extremely *mild form*, or with but little constitutional disturbance,—the appetite, pulse, and mental powers being scarcely affected; and in this form it may continue long, or soon disappear, sometimes after very inefficient means of cure, or even without the use of any medicine. The liability of the disease to recur from slight causes — as errors of diet, intemperance, &c. — has sometimes given it an apparently *periodical* character, which, although contended for by some authors, is entirely accidental, or, at least, the consequence of a concurrence of several of its causes, at certain seasons or periods, especially in situations abounding in the sources of endemic maladies.

15. II. CAUSES.—i. The *Predisposing Causes* are indolence, dissipation, intemperance, and sedentary occupations, particularly those performed in a stooping posture, and with pressure on the hypochondria and epigastrium. Jaundice is not infrequent among the studious; and especially amongst those who are harassed by cares, disappointments, and the depressing passions, and whose nervous energies are exhausted. It seems also more frequent in hypochondriacal and hysterical persons, and those who neglect, or are deprived of, their usual active engagements. It is common to all ages and sexes. HEBERDEN found, that out of 100 successive patients with this disease, 52 were males. It is frequently met with in cooks, and bakers, and in workmen exposed to high ranges of temperature, or addicted to intoxicating liquors. In females, it is oftener observed during pregnancy, and after the cessation of the catamenia, than at other epochs.

16. ii. The most common *Exciting Causes* are the more violent mental emotions, as the sudden communication of distressing intelligence, fright, terror, rage, anger, grief, anxiety, despondency, losses and disappointments, jealousy, petulance, peevishness, and irritability of temper. I have known it to follow the communication of joyful intelligence. Particular kinds of ingesta, especially such as disagree with the digestive organs, as stale, unseasonable, and unwholesome fish; drinking cold fluids when the body is perspiring; cold applied to the feet and surface of the body after exertion, or during free perspiration; and the bites of animals, particularly those which are venomous; also occasionally produce jaundice, especially in those who have experienced a former attack. According to HOFFMAN, venereal excesses, and intemperance in the use of intoxicating liquors, are amongst the chief causes of the disease. Great debility and exhaustion of the nervous energies, and, as clearly demonstrated by Dr. CHEYNE and Dr. MARSH, mercurial courses, particularly when employed in hospitals and close apartments, sometimes occasion it. I believe, however, that mercurials are a cause, only when they are given to produce their specific effects, or, when the exhibition of purgatives has been neglected, when required. The prevalence of the disease during revolutions, invasions, sieges, and campaigns, has been remarked by many writers; and its occurrence after intemperance in eating or drinking must be familiar to all. The excessive use of coffee; austere, and acid, or unripe fruits; and, indeed, any error of diet, or deleterious substance received into the stomach; will sometimes produce it. The suppression of accustomed discharges and eruptions, and the retrocession of rheumatism and gout, also not infrequently occasion it.

17. When the pathological conditions of the biliary and digestive organs exist, with which this disease is most frequently connected, many causes, that under different circumstances would produce but little effect upon the system, will readily excite it. Severe pain, mental affections, an irritating purgative, or particular kinds of food, will sometimes be sufficient to give rise to an attack, especially when pre-existing disorders of the biliary organs is associated with great nervous exhaustion. Jaundice is not infrequently caused by obstructed circulation through the heart; and by a torpid state of the cæcum and colon, with accumulations of fæces and scybala in their cells. It often follows agues and other periodic fevers; and it then usually depends upon some one of the morbid states of the liver, already noticed. It often occurs in the course of bilious remittent fevers, and occasionally without any apparent diminution of the biliary discharge, and even with evidence of augmented secretion of bile. It is also often associated with dysentery, or with other diseases, as will be shown in the sequel.

18. III. The MORBID APPEARANCES most frequently found in persons who have died *with* jaundice, are the following: — *a*. The *surface of the body* generally preserves the same colour after death, as previously to dissolution. PORTAL and myself, however, have seen the intensity of colour diminished; and, in other instances, the skin of some subjects, who had never had jaundice, assume, after death, a deep yellow. The limbs are often flexible, and œdema of the extremities is not infrequent. The body is commonly emaciated. The serum in the œdematous limbs, as well as that in the internal cavities, is either of yellowish tint, or of a dark hue. The various structures are more or less tinged of the same hue, particularly the cellular, adipose, and serous tissues. The internal surface of the blood-vessels, and even the cartilages, tendons, periosteum, and bones, are sometimes also changed in colour. The muscles are often tinged, and softer and more flaccid than natural. MORGAGNI had re-

marked, that the substance of the lungs, heart, liver, kidneys, and spleen is often softened, and contains a yellowish, a greenish yellow, or reddish fluid; and subsequent observers have also noticed these appearances. Most of the *secretions* partake of the same tinge; and the serum of the blood is also similarly altered. The fluid effused into the ventricles of the brain and all the membranes, are thus changed; but the substance of the brain itself, and the humours of the eye, are generally of their natural colour.

19. *b*. The *liver* and its appendages, most frequently of all the viscera, present morbid changes. The liver itself has been found with all the lesions consequent upon every form of inflammation. It is sometimes greatly enlarged, its blood-vessels congested, its ducts engorged, and its structure softened, inflamed, deeply tinged, or suffused with bile, and containing one or more abscesses, or their remains, &c. At other times it is extremely pale, apparently devoid of blood and of biliary secretion, atrophied, hardened, scirrhous, and tuberculated. In one case it is changed to a white, parboiled state; in another converted into a fatty, steatomatous, tallowy, or adipocerous substance. Occasionally its ducts are loaded with green inspissated bile, obstructed by concretions of cholesterine or of resinous matter. In other instances they are entirely empty, or contain merely a little thin, pale fluid. Sometimes the surfaces of the liver adhere to the adjoining viscera, and collections of matter or large abscesses press upon them, or upon the bile ducts, or open into the latter, or into other parts. In a few instances the *hepatic veins* have been found more or less obstructed, or pressed upon by tumours or enlargements of adjoining parts. In one instance of jaundice connected with abscess of the liver, I detected inflammation of these veins, several of them being plugged up with lymph, or filled with pus. In rarer instances, hydatids are found in the liver, or attached to it. (See art. Liver.)

20. *c*. The *gall bladder* often contains *calculi*, the number and size of which are very various. When one only is found, it is usually very large. The gall bladder may be distended with *bile*: in this case the fluid is much changed; being generally of a deep green colour, or greenish black, thick and ropy, and sometimes containing granular matter. In some instances, the accumulated fluid is of a pale orange colour, and thin consistence. A portion of fluid of this description, which was taken from a subject dead of tuberculated liver, jaundice, and dropsy, was examined by Dr. Bostock, and found to consist of water, albumen, and a little colouring matter, without any of the usual biliary principles. Stoll found the gall bladder filled with a whitish serum. In other cases it is entirely or nearly empty. Sometimes marks of inflammation are observed in its coats. The last named author found them changed to a semicartilaginous state. Frank, Louis, and Andral met with ulceration of the internal surface, with softening of the coats of the gall bladder; and a similar case occurred to myself, where it contained gall-stones. Andral found it softened and ruptured. Excrescences into its cavity have been noticed by Bonet. Adhesions of it to the adjoining parts are occasionally observed. Its entire absence in this disease occurred to M. Bourgeoise; but this is merely a coincidence. In a case of absence of gall bladder in a patient at the Infirmary for Children, there was no jaundice; and similar facts have been observed by others.

21. *d*. The *biliary ducts* are frequently obstructed, in some cases by gall-stones, in others by the pressure of tumours in the pancreas, mesentery, pylorus, or duodenum. The common duct is not infrequently obstructed by scirrhous or other tumours in these situations. In this case, as well as when it contains calculi, the gall bladder, and the duct above the seat of obstruction, are generally greatly dilated, and filled with thick, dark-coloured bile. This dilatation sometimes extends more or less throughout the ramifications of the hepatic ducts. In a case which occurred in my practice some years ago, and where both the common and the pancreatic ducts were completely obliterated by their inclusion in a large, hard, or scirrhous tumour, developed between the root of the mesentery, and head of the pancreas, — this latter being remarkably enlarged, — the gall bladder contained about twelve ounces of this kind of bile, and the ramifications of the ducts through the liver were much dilated. The coats of the ducts sometimes exhibit marks of inflammation, — are ulcerated, thickened and indurated, and the calibre of their canals are much reduced. In some instances, the ducts are entirely obliterated, and reduced to a thin fibro-cellular cord. This obliteration I have seen confined in one case to the common duct, in another to the cystic duct. In the latter instance, the gall bladder was enormously distended with a deep green viscid bile: the obliteration of the duct must have been subsequent to the accumulation of the secretion in this reservoir. Stoll, Portal, Andral, and others observed a cartilaginous state of both the common and cystic ducts. Lieutaud, Ludwig, and Chapman found lumbrici in the common duct, in icteric patients.

22. *e*. The *stomach* is not infrequently seriously altered, particularly when the disease has been occasioned by intemperance, especially in the use of spirits. The pylorus in those cases is sometimes thickened, cartilaginous and greatly constricted (Stoll). — The *duodenum* is often, also, the seat of lesion, especially in the vicinity of the ducts. It is sometimes inflamed, thickened, softened, or indurated, ulcerated, and, in rare cases, apparently scirrhous. Tumors of various kinds have involved its coats, at the place where the ducts enter it, either entirely obliterating their apertures, or very greatly diminishing them. Oechy found this viscus remarkably dilated, so as to press upon the ducts. The *pancreas* is occasionally enlarged, scirrhous, or otherwise altered, — pressing upon, or obstructing, the ducts. Great enlargement of the *right kidney* has also produced this effect. The *spleen* is sometimes enlarged, or otherwise altered.

23. *f*. Alterations of the *vena portæ* are also met with in jaundice. M. Honoré found this vessel nearly impervious. It has been observed considerably enlarged throughout its ramifications, and congested with black blood. In a great number of icteric cases, the viscera adjoining the gall bladder are much stained by the exudation of bile through its coats. But this is an entirely *post mortem* appearance. — *Dropsical effusions* into the

various cavities are frequently met with, and occasionally coincident lesions in the *heart*, *lungs*, as well as in some one or more of the abdominal viscera.

24. It should not be overlooked, that each, or several, of the foregoing lesions have often been present without jaundice,— a circumstance which has led some pathologists to deny the origin of it in the presence of bile in the circulation; and that jaundice has existed in patients, in whom no organic lesion was detected after death,—an occurrence which has led physicians, since the times of HOFFMANN and MORGAGNI, to impute the disease, in some cases, to spasm of the biliary ducts, and induced others to view it as an occasional consequence of the accumulation in the blood of the materials of which bile is formed, owing to inaction of the liver. But there is every reason to suppose that undetected disease of the heart had existed in many of these, and had obstructed the return of blood from the liver.

25. In cases of jaundice, particularly in those of long standing, a yellow or greenish yellow tint, in different degrees, is usually observed in every texture and organ of the body, and in all the fluids and secretions, whether natural or morbid. The fat is usually of the deepest colour. The humours of the eye and the cornea are seldom or ever tinged. A case is, however, related in HORN's *Archives* (*Für Pract. Medicin.* b. vi. p. 341.), where they exhibited this change of colour. The yellow hue has rarely been detected either in the cerebral structure, or in the medullary tissue of the nerves; although instances have occurred to BARTHOLIN, MORGAGNI, and PORTAL, of its appearance in the former.

26. IV. OF THE PATHOLOGICAL RELATIONS OF JAUNDICE.—Jaundice is more or less intimately connected with one or other of the following pathological conditions: — 1. With an exuberant secretion of bile; — 2. With inflammation and abscess of the liver; — 3. With congestion of the liver and portal system; — 4. With chronic alterations of the structure of the liver; — 5. With spasm, or temporary obstruction of the gall ducts; — 6. With the passage or existence of gall-stones; — 7. With inflammation, obliteration, or compression of the biliary ducts, or gall bladder; — 8. With inflammation of the duodenum.

27. i. *Jaundice with Exuberance of Bile.*—This variety was first contended for by M. PORTAL, and afterwards by MM. CORNAC, ALIBERT, VILLENEUVE, and others. It has been referred to an excited state of the vital actions of the liver, particularly to the predominance of its secreting function. It is sometimes met with in temperate climates, during summer and autumn, especially those which apppoach nearest the tropics; but it occurs chiefly in warm or intertropical countries, and in those who live indolently and luxuriously or intemperately, or who are of a bilious temperament. It is generally preceded by supraorbitar headach, bitter taste in the mouth, loss of appetite, nausea, bilious vomiting, followed by a yellowish, or greenish yellow tint of the skin. The chief characteristic of this form of the disease is the absence of constipation, and the presence of bile in the evacuations, which are either natural, or more frequent than usual. I have seen it accompanied with slight bilious diarrhœa, with febrile action, or with a full or strong pulse. It may be presumed, that a portion of the bile is absorbed in this variety, during its course through the biliary passages, or through the intestinal canal, owing either to increased activity of the absorbing vessels, to the state of the bile itself, or to partial obstructions in its course through either of these parts. It is often complicated with dysentery, hepatitis, and bilious fevers, particularly in miasmatous and intertropical countries.

28. ii. *With Inflammation and Abscess of the Liver — Hepatic Jaundice*, SAUVAGES and CULLEN —*Icteritia Pyrexica*, ALIBERT.—Jaundice may accompany any form of inflammation in this organ, particularly when the internal structure is the seat of the morbid action. Although inflammations of the liver are so extremely frequent in India, yet jaundice is a comparatively rarer attendant on them there, than in this country. In Continental countries, this association of jaundice is very common. The rare occurrence of jaundice, as a symptom of hepatitis, in India, is perhaps owing to the liberal use of calomel in the treatment of hepatic affections. But it is when abscess forms in the liver, that we most frequently find jaundice supervene on hepatitis. In a very large proportion of the cases of abscess of this viscus, detailed by M. ANDRAL (*Clinique Médicale*, t. iv.), jaundice appeared;—and a similar frequency of connection has occurred in my own practice. Out of six cases of abscess of the liver to which I was called, in 1826 and 1827, in consultation, four had jaundice during some period of their progress, subsequently to the occurrence of the symptoms indicating the formation of matter.

29. In almost every case of jaundice from inflammation or abscess of the liver, the nature of the disease is very readily recognised. The symptoms of hepatitis are well marked, particularly the pain, uneasiness, and tumefaction in the right hypochondrium and epigastrium; the scanty, dark, or brownish urine; the dry cough; the pain in the right shoulder, clavicle, and side of the neck, or under the right scapula, &c.; and the full and frequent pulse, &c. (See LIVER —*Inflammation of*, and *Abscess of.*)

30. iii. *Jaundice from Congestion of the Liver — Intemperies calida, of* SENNERT — *Icterus a Plethora*, of F. HOFFMANN. — The connection of this state with jaundice has been admitted by SAUVAGES, GRIMAUD, BANG, PORTAL, CORNAC, and MANOURY. It is generally observed in persons of the bilious and sanguine temperaments, who live luxuriously or intemperately, and either pursue sedentary occupation, or are deprived of requisite exercise. It is chiefly to this and the preceding pathological states, that we are to refer the instances of jaundice, which take place from the suppression of the menses, or of accustomed discharges, particularly the hæmorrhoidal, and from the retrocession of gout and rheumatism. Active congestion of the portal vessels is connected with more or less plethora, and congestion, of all the vessels that convey blood into the vena portæ. The blood circulates with difficulty through the liver; and the bile, which is formed, generally in great abundance, owing to the highly venous state of the blood, often is retarded and accumulated in the ducts, during its course to the gall bladder or duodenum. Owing to this retardation or obstruction, a portion of it is absorbed, probably by the radicles of the hepatic veins, as they pass out of

the granular structure, where the biliary secretion is performed, and the ducts take their origin. It is obvious, that obstructions of the return of blood from the liver, owing to *organic lesion of the heart*, will also give rise to this form of the complaint, and that such occurrences are not rare.

31. iv. *With Chronic Organic Alterations of the Liver — Aurigo ab Obstructione*, Sauvages—*Icteritia Apyrectica*, Alibert. — In this form of the disease, the accession of the jaundice is generally very slow; the colour is livid or dusky, permanent, and often extremely deep, approaching sometimes a greenish or olive hue, forming the green or black jaundice of several authors. The organic alterations vary remarkably; consist of those already enumerated (§ 18. *et seq.*); and are often complicated with lesions of the adjoining viscera, or with dropsical effusions. In the majority of these cases, the bile seems either to be secreted with morbid properties, and to be conveyed into the circulation almost as soon as it is secreted; or, what appears still more probable from the morbid appearances very frequently detected, the materials of which bile is formed, are not combined by the liver, and converted into bile, but, having experienced the preparatory change, merely pass onwards from the granular structure of the liver into the radicles of the hepatic veins, and, circulating with the blood, tinge the textures of the body, particularly the rete mucosum. That there is sometimes no due secretion of bile, is shown by the secreting structure of the liver being often found either completely destroyed, or so altered, as not to admit of the demonstration of its peculiar texture; and also by the pale, straw-coloured, tasteless, and albuminous serum found in the ducts (§ 19.); or by their empty, atrophied, and pale states. This variety of jaundice is generally the consequence of intemperance, or of residence in miasmatous districts, or in warm climates. It is often observed in persons of middle age, or somewhat further advanced in life; and is preceded by chronic dyspeptic or bowel complaints; and by indications of disorder in the liver, often of many years' duration.

32. v. *Jaundice from suspended Function of the Liver, or from Spasm of the Ducts —Icterus a Spasmo*, Hoffmann.—That jaundice ever proceeds from spasm of the gall ducts, has been denied by several writers. Cullen, Powell, Andral, and Jourdan have, however, contended, that spasm of the ducts sometimes occurs, and produces the disease, especially in cases arising from mental emotions, and the irritation of the upper portion of the intestinal canal. Sudden mental affections, — as fright, terror, rage, anger, disappointment, excessive joy, — frequently occasion a most painful and oppressive sensation at the epigastrium, faintness or difficulty of respiration, and paleness of the countenance. This state is occasionally followed almost instantly, but always in a very short time, by yellowness of the face and surface of the body. In some cases, the functions of the brain are much disturbed, and a febrile state of the system takes place. In others, nausea, vomiting, &c., in addition to the icteric affection, are produced. In these, the moral affection influences the state of the nerves proceeding from the solar plexus; and hence the morbid sensations referred to the epigastrium. The slow depressing passions of the mind were also supposed, particularly by Villeneuve and Manoury, to occasion spasm of the ducts; and physical pain was considered by M. Portal occasionally to operate in a similar manner. When jaundice is connected with hysteria, epilepsy, or hysteralgia, Hoffmann referred it to the same cause. Even the bites of venomous reptiles were supposed by Mead and Bosquillon to produce icterus in a similar way. Bartholin, Lanzoni, and Van Swieten have imputed the rare occurrence of jaundice from the bites of dogs, or other animals, also to this circumstance.

33. Cases of this kind admit of a different explanation from that proposed by the above writers. It is more probable that violent mental emotions, and that sedative poisons taken into the stomach, or inserted into the tissues, suspend the organic nervous influence, and thereby arrest the functions of the liver, than that they occasion spasm of the ducts and adjoining parts. That this latter state, however, may occur, I will not deny, especially when nausea, retchings, or vomiting are added to the icteric affection, or when the duodenum is irritated in the vicinity of the ducts. The more or less complete paralysis of the biliary organs, produced, for a time, by the causes alluded to above, favours the absorption or passage of bile into the circulation, and the accumulation in the blood of the elements of which bile is formed.

34. The principal characteristics of this variety of jaundice are its rapid appearance and short duration. It is seldom deep, and generally is of a pale yellow, or bright yellow hue. It often disappears without the aid of medicine; and the treatment resorted to, in such cases, thus obtains a reputation it does not deserve.

35. vi. *With Inflammation and Obliteration of the Ducts and Gall Bladder.* — The ducts may be inflamed, and obstructed in consequence of the turgescence accompanying the inflammation, or as MM. Jourdan and Breschet have stated, of some degree of spasm attendant on it. The inflammatory action may also extend to the gall bladder, or be almost entirely limited to it. Inflammation and its consequences have been observed after death in one or other of these situations, both in connection with, and independently of, jaundice; and have most probably been induced by the irritating properties of the bile passing through the ducts, or by the extension of inflammatory action from the internal surface of the duodenum to that of the common duct. In either circumstance, the ducts above the obstruction may become dilated, although not to the extent observed after obstructions of a more permanent kind. If, however, the consequences of inflammation furnish a permanent obstruction, this result will often occur.

36. In cases of this kind, the patient has more or less fever, dry skin, thirst, and anorexia or nausea, or even retchings. Pain is felt in the right hypochondrium, particularly under the exterior and inferior angle of the right shoulder blade, extending to the epigastrium, on the right side of which, or beneath the extremities of the right false ribs, a pyriform moveable tumor is sometimes felt. The stools are without bile. More or less fulness of the right hypochondrium and epigastrium is also often present, sometimes with pain not only in the above situations, but also in the back, and in distant parts. These

symptoms may continue an indefinite period with various degrees of severity; and may subside with the jaundice after a time, upon the resolution of the inflammation.

37. In less favourable cases, owing to the thickening consequent upon the inflammation, or to the exhalation of coagulable lymph from the internal surface of the inflamed duct, together, perhaps, with spasm, its canal becomes permanently obstructed, and the vessel is ultimately reduced to a fibro-cellular cord. In these, the jaundice generally continues, and all the digestive and assimilating functions languish; death ultimately taking place.

38. vii. *Jaundice from Compression of the Ducts by Tumors, &c.* — The lesions of the adjoining viscera already referred to (§ 21.), particularly the formation of scirrhous and other tumors in the pancreas, pylorus, mesentery, &c. involving and obliterating the ducts; enlargement, and disease of lymphatic glands in the vicinity of the common duct; engorgement or inflammation of the pancreas, occasioning compression of this duct; great enlargement of the right kidney; distension of, or accumulations of hardened fæces in, the cæcum and colon; the gravid uterus, &c.; may occasionally interrupt the passage of bile into the duodenum, by pressing upon the ducts, and thus occasion jaundice. It is only by pressing scybala, or hardened fæces lodged in the cells of the colon, upon the duodenum and common duct, that the gravid uterus causes jaundice. It is extremely difficult to ascertain the presence of any of those causes during the life of the patient; although suspicions of the existence of some of them may be entertained from the *tout ensemble* of the symptoms, and the effects of remedies. When jaundice arises from accumulated fæces, the effects of purgatives will often demonstrate its origin. The frequency of this cause has been justly insisted on by Van Swieten and others.

39. viii. *Jaundice from Calculi in the Ducts — Aurigo Calculosa*, Sauvages. — Calculi lodged in the ramifications of the hepatic duct, may occasion, or rather be connected with, jaundice; but their presence in the common and cystic ducts is a more frequent cause. They are more rarely found in the hepatic duct, but they may produce the disease in that situation. Their impaction in the cystic duct, even when the gall-bladder is filled with dark bile, does not uniformly occasion this affection, as shown by numerous observers. When they obstruct the common duct for some time, this effect very generally, although not always, follows; and the symptoms, particularly when the calculus approaches to, or is passing through, the coats of the duodenum, are often very well marked. In many cases, however, calculi pass without giving rise to jaundice, or, indeed, to any very prominent symptom or ailment; and in others, they pass with violent sufferings, and yet no jaundice is occasioned.

40. More commonly the occurrence of jaundice from the impaction of calculi in the bile ducts, particularly the common duct, is attended with pain, weight, pressure, and uneasiness towards the epigastrium, especially when the patient lies on the left side. Acute, colicky, and spasmodic pains are felt at intervals in the region of the duodenum, under the right shoulder blade, and extending to the hypochondrium and epigastrium, followed sometimes with nausea, vomiting, and a sense of heat at the stomach. Occasionally, a tumor is detected between the epigastrium, hypochondrium, and umbilicus. When the fits of pain are violent, the patient often complains of vertigo, of the extension of the spasm to the abdominal muscles, and even to the extremities. There is seldom only one calculus, generally several; and the attack is often renewed upon the passage of each, with a varying degree of severity according to their size. The jaundice in these cases may precede, or even follow, the painful symptoms. Upon the discharge of the calculi, these symptoms quickly subside; but the jaundice disappears only slowly, or even persists for some time.

41. The production of jaundice by the presence of *worms in the ducts* has been stated by several authors, and doubted by others. Dr. Chapman refers to a preparation demonstrating the fact in the museum of the University of Pennsylvania.

42. ix. *Jaundice from Inflammation or Congestion, &c. of the Internal Surface of the Duodenum.* —Various deleterious ingesta, acrid salts and poisons, emetics, and purgatives, articles of food which offend the stomach, drinking cold fluids, &c. when the body is overheated, or exposure to cold, have been supposed by Broussais and his followers sometimes to occasion so much inflammation and turgidity of the mucous membrane of the duodenum and adjoining parts, particularly about the orifice of the ducts, as as entirely to occlude it, and thereby to give rise to jaundice. That this takes place in rare cases, or that congestion in this situation will have the same effect, may be admitted, although satisfactory proofs of the circumstance cannot be readily furnished. The inflamed and turgid state of the duodenum may be limited to it, or may even extend to the ducts, as stated above, and thus cause obstruction (§ 35.). The jaundice accompanying bilious fevers and dysentery may depend upon this pathological state.

43. It is probable that this variety of jaundice will be attended by very nearly the same symptoms, as characterise that proceeding from inflammation of the ducts; but that, unless the ducts become implicated, the jaundice will be less marked, and of shorter duration, than when they are inflamed. The presence of nausea, vomiting, or of diarrhœa, or of sympathetic phenomena, in such cases, furnishes but slight evidence of this pathological state. Oechy states that he has seen the duodenum dilated so as to press upon and obstruct the ducts, in a case of jaundice; but there was probably some other lesion upon which the jaundice more immediately depended than upon this.

44. Various other morbid states of the duodenum may occasion jaundice, particularly the accumulation of mucus on its surface, or about the orifice of the ducts; and various organic lesions seated in this part, or extending to it, or to the ducts from adjoining viscera. The former of these is probably not an infrequent cause of the slighter and less enduring kinds of jaundice, particularly in infants (§ 53.), children, and young persons.

45. V. Jaundice from Suspension or Arrest of the Secreting Function of the Liver — *Pseudo Jaundice.* — In this form of dis-

ease, which cannot be considered as a variety of true jaundice, bile is not secreted or formed from its elements in the blood, owing either to a paralysed or suspended state of the vital action of the liver, or to disorganisation of it to an extent entirely subversive of its functions. In either case, the elements, from which the bile is formed, accumulate in the circulation, change the colour of the serum and of the blood generally, and thus render the skin lurid or murky. In a further advanced stage of the disorder, certain of the principles, or even the colouring matter, of bile are fixed, or deposited, in the tissues, imparting to them either a darker, or a more jaundiced hue. (See art. Disease, § 108.) The slighter states of this form of disorder frequently accompany torpor of the liver, as observed in this country; and the more marked states of it often occur in miasmatous and warm climates. In various fevers also, and in some epidemics and pestilences, the action of the liver is entirely suspended; the surface becoming dark or lurid. This takes place to a remarkable extent in *pestilential cholera*, and is heightened by other circumstances.—When this state of disease arises from disorganisation of the liver, its accession is slow, and the discoloration of the surface often proceeds through a dirty or lurid hue to the greenish or greenish black colour about to be noticed. In either of the pathological states producing the discoloration, there is an entire absence of bile from the stools; and the secretions from the kidneys and skin are dark, or otherwise altered, from the presence of the elements or of the principles of bile.—When the vital power of the organ is suspended, there is seldom pain or other prominent symptom detected in the region of the liver. There is even sometimes an unusual absence of symptoms indicative of acute hepatic disease, excepting the complete suspension of the functions of the organ. But when the structure of the viscus is so altered, as to be incapable of discharging its offices, the antecedent disorder, as well as the attendant phenomena, will generally indicate the pathological relations of the affection, aided by the history of the case, and a knowledge of the causes. The alterations of the liver, already noticed in connection with true jaundice (§ 19.), will occasionally, when carried to the highest pitch, give rise to this form of the disease, or to the next to be noticed (§ 46.).

46. VI. Of Green or Black Jaundice—Μελαίνα νοῦσος, Grec.—*Icteritia nigra*, Forestus — *Icterus viridis*, *Melas Icterus*, *Melanchorus*, Fennel, et Var. Auct.—*Icterus Melæna*, Good — *Green Jaundice*, Baillie — *Black Jaundice*. — This is merely the extreme grade of the disease. It was first described by Aretæus; but although somewhat circumstantially noticed by several authors, the first satisfactory account of it was furnished by Dr. Marcard and Dr. Baillie. The colour of the skin varies in depth from a yellowish green, to a deep green or olive colour. The temperature of the surface is not increased; but burning heat is felt in the palms of the hands, and soles of the feet. The evacuations are often pale; but sometimes they are dark coloured, pitchy, with grumous coffee or chocolate like matter, and slight diarrhœa. The urine is occasionally clear, but oftener very dark and loaded, tinging the linen of a dark, tawny hue. The patient is greatly depressed, physically and morally, and complains of anxiety at the epigastrium, and of tenderness either in that situation, or in one or both hypochondria. A sensible enlargement of the liver is often felt, and sometimes also of the spleen. In a case which I lately treated, both these viscera were very remarkably enlarged. But an opposite state as frequently obtains. The pulse is usually natural or slow. Vertigo, sickness, and vomiting of a green, acid colluvies, occasionally are present. In the intervals, the appetite is either capricious, or but little affected.

47. This form of jaundice seldom attacks young persons. It is commonly met with in the aged or advanced in life, and is much more frequent in males than females, particularly in those who have lived long in unhealthy intertropical countries, or who, with great anxiety and fatigue, have been tried by frequent changes of climate. It is generally connected with the most chronic and profound organic lesions of the liver, especially those which involve, or destroy, its secreting structure, and obliterate the minuter ramifications of the ducts through the organ. It seldom admits of more than a partial removal, but terminates in either a fatal exhaustion, or with coma, apoplexy, epilepsy, or palsy. Abdominal dropsy frequently takes place in its progress. Its course, in its slighter grades, is generally slow,—sometimes continuing, with various fluctuations, for seven or eight years; but when the colour becomes very deep, it often terminates rapidly, in either of the above ways.

48. When green jaundice is attended with pitchy, or dark, grumous evacuations, there is generally either a congestion of the spleen, and of the portal system of vessels, with the secretion of a dark-green unhealthy bile, a portion of which is absorbed, and deposited in the structures, particularly in the *rete mucosum*; or a congested and hæmorrhagic state of the mucous membrane of the stomach, duodenum, and upper part of the intestines, owing to the obstructed circulation through the liver; but both pathological conditions may be present, giving rise to an exhalation of venous blood from this membrane, and thereby to the dark and grumous motions. The mucous membrane in these situations is usually found, on dissection, dark-coloured, mottled, softened, ecchymosed, or its venous capillaries loaded. The other viscera, particularly the *liver* and *ducts*, present the appearances already described (§19, 20.).

49. VII. Complicated Jaundice. — By this appellation, I mean the occurrence of jaundice — 1. during the course of some other disease; and, 2. upon the subsidence or suppression of a pre-existing disorder, which may not only be concerned in its appearance, but also in its removal or recurrence. — *A. The maladies during the progress of which jaundice most commonly occurs*, are chiefly those fevers which implicate, in a more or less marked manner, the liver and digestive mucous surface. Thus it is frequently observed in the course of *gastric*, and of *bilious remittent fevers*, of both an inflammatory or low character. It is also not infrequent in connection with *ague*; and, owing partly to this circumstance, it has been said by some authors to recur *periodically*. Its appearance in the course of *typhus fevers* is

comparatively rare. MENDE has sometimes remarked it; and CHEYNE notices its infrequency. When it occurs during *fevers*, it may be imputed either to diminished excreting activity of the liver, and the rapidity of absorption of a portion of the secretion, or to obstruction in the way of the opening of the ducts into the duodenum, from a tumefied, congested, or inflamed state of its mucous surface. In some cases, both states may contribute; whilst in others, the secretion takes place more rapidly than it is conveyed into the bowel, although its flow is in no respects impeded. The secreting function of the organ may also be much diminished, — the constituents of bile being left in the blood.

50. We occasionally also observe jaundice in connection with *organic lesions of the heart*, *hysteria*, *dropsy*, *melaina*, *delirium tremens*, *apoplexy*, *palsy*, and *epilepsy*. — When it is complicated with *hysteria*, the urine is usually very abundant and limpid, and the complication is of a much less serious nature, than with the other maladies just named, which more frequently terminate unfavourably, when thus associated. — When it occurs in consequence of interrupted circulation through the heart, dropsy, or hæmorrhage, often also supervenes. We also not infrequently hear of it in connection with certain *cachectic* and *malignant affections* of a chronic character. Several of the states, which are usually attributed to jaundice, in the last stages of these maladies, are not true jaundice, and do not proceed from the presence of bile, or of its constituents, in the circulation; but from the absorption, and admixture with the blood, of a portion of the morbid matters formed in the seat of the local or malignant affection, or of some of the morbid secretions retained in the digestive canal (§ 54.).

51. *B.* Jaundice sometimes follows the subsidence or suppression of other diseases, and is even removed by the reproduction of certain of them: it often appears after periodic fevers, and occasionally upon the sudden arrest of these fevers by large doses of cinchona or of sulphate of quinine, especially when these are exhibited before morbid secretions or accumulations have been evacuated. In such cases, the jaundice depends chiefly upon superinduced congestion or inflammation of the internal structure of the liver. The stoppage, also, of *hæmorrhoids*, sometimes gives rise to jaundice, by inducing these morbid conditions of this organ; the re-establishment of the hæmorrhoidal flux generally removing the congestion, and favouring resolution of the inflammatory action. A similar result occasionally occurs from obstruction of the catamenia, and from suppression of dysentery, diarrhœa, of gout, and of rheumatism, especially when morbid secretions, and collections in the digestive canal, have not been removed. The relation of gout to several of the pathological states which give rise to jaundice, and the conversion, in some instances, of the one into the other, have been remarked by several experienced physicians; and a similar connection has been noticed between this latter and the other diseases just named.

52. VIII. TRAUMATIC JAUNDICE. — Jaundice sometimes occurs after concussion of the brain, and severe injuries of the head. The influence which the brain exercises on the functions of the liver, has been oftener the subject of remark than of explanation. It has usually been imputed to sympathy; or, in other words, the morbid relation has been stated, and our ignorance of its nature admitted at the same time. Severe injuries, when they suspend the energies of the brain, may also lower the secreting and excreting functions of the biliary apparatus, by diminishing its nervous energy, and placing it in a state which (§ 33.) favours the absorption of bile into the circulation, independently of any very obvious change in the structure of the liver or ducts. There is, however, every reason to suppose that jaundice subsequent to severe injuries, particularly of the head, sometimes results from phlebitis, originating in the seat of injury, or from the passage of purulent or other morbid secretions thence into the circulation. In either case, purulent collections will sometimes form in the liver, and give rise to jaundice by pressing upon the hepatic ducts and veins. Severe injuries in other situations than the head, — as compound fractures, &c., — will sometimes also produce the same results. That purulent collections form in this viscus, under these circumstances, almost as frequently as in the lungs, is a fact fully established by the observation of the author, and other pathologists; and although jaundice is not a constant, yet it is a very general, attendant upon them. — Injuries, wounds, &c., which implicate any part of the biliary apparatus, occasionally produce jaundice, by the immediate change they induce in the functions or structure of it; and it is not unlikely that, in some of the instances where the injury seemed to have been inflicted on the head, the liver actually had sustained the chief injury, or had experienced a concussion, of which jaundice was the consequence, either with, or without, inflammatory action diffused through the substance of the organ. — When jaundice follows blows or injuries on the region or vicinity of the liver, and especially if it be attended by a dull or aching pain, inflammation extending through the substance of the organ may be inferred to exist.

53. IX. INFANTILE JAUNDICE — *Icterus Infantum* — *Icterus Neonatorum* — *Yellow Gum*. — Jaundice is usually slight during the infantile age. It is generally attended with languor, drowsiness, or debility; and may be referred to the following pathological states: — 1st. To the stagnant and altered blood contained in the umbilical vein, changing the state or colour of the serum; — 2d. To a partial absorption, from retention of the meconium; — 3d. To saburræ accumulated in, and absorbed partially from, the duodenum and small intestines; — 4th. To obstruction of the aperture of the ducts from viscid meconium, and mucous sordes; — 5th. To spasm of the excretory biliary ducts (BEAUMES); — 6th. To a superabundance of the biliary secretion: — and, 7th, To obstruction, or a paralysed state of the secreting structure of the liver. The first, second, and third of the above sources may so change, or deepen the colour of, the serum of the blood, independently of any absorption of bile, as to give rise to the yellow state of the cutaneous surface frequently met with in infants. — Superabundance of the biliary secretion may exist in more than one respect; — this fluid may be secreted in unusually large quantity, or it may have accumulated in the ducts and gall bladder during the period immediately antecedent to birth, or it may have flowed into the duodenum in very large quantity, and

mixed with the secretions of the digestive mucous surface, forming a meconium, abounding more than usual in biliary principles, instead of the bland albuminous fluid, which is usually formed for the purpose of assisting fœtal nutrition and growth.— A paralysed state of the secreting structure of the viscus has been ascribed by M. BEAUMES to injury sustained by the brain during child-birth, but it may exist independently of this cause. One or more of the above pathological states may give rise to jaundice in infants, which is generally mild, and readily removed by medicine. It usually occurs very soon, or within the first week, after birth, particularly when the bowels have been neglected; but it may appear at any period. When it comes on within the first week after birth, it seldom continues above four or five days, and is usually slight.

54. X. OF CACHECTIC OR SPURIOUS JAUNDICE. — Morbid secretions readily pass into the circulation in the course of various malignant, pestilential, and cachectic maladies, and impart a dark or dirty hue to the serum, and otherwise affect the blood, producing a similar tinge in most of the tissues, — the cutaneous surface closely approaching the colour of jaundice, but differing from it, in being more lurid and dusky, and in the absence of biliary obstruction. In low states of vital power, morbid secretions may be absorbed from the digestive canal, and thus affect the circulating fluids; and in a similar state of vital power, secretions or morbid matters in other situations, as from the uterus in the puerperal state, from abscesses, from disorganisation of the cellular tissue, &c., may pass into the circulation, and impart a lurid or jaundice-like tinge to the external surface and other parts. The contamination of the fluids and soft solids in the latter stages of chronic malignant maladies, as carcinoma, fungoid disease, is also attended by a change of the cutaneous surface resembling jaundice, but essentially differing from it. For the hue of the skin in these maladies proceeds from the admixture of morbid matters absorbed from the seat of local mischief, vitiating and tinging the serum of the blood of a deeper hue, and thereby rendering darker the *rete mucosum*; and not from the presence of bile, or even of its chief constituents, in the circulation (§ 63. *b.*). The lemon, yellowish, or even the yellowish green hue of jaundice, is very different from the lurid, dirty, or murky appearance of the surface consequent on these maladies. In these, the pale or clayey state of the stools, and the saffron tinge communicated by the cutaneous and urinary secretions in jaundice, are wanting, whilst the alvine evacuations are usually dark, morbid, and very offensive.

55. The appearance of the cutaneous surface in *chlorosis* resembles a slight attack of jaundice; and it is necessary not to mistake the one for the other. This will be avoided by attending to the age, the functions of the uterus, and to the evacuations. In chlorosis, the discharges are more natural than in jaundice, the perspiration and urine not communicating to the linen the saffron tinge observed in the latter complaint. In chlorosis also, and, indeed, in the latter stages of chronic malignant diseases, the waxy state of the integuments, and the smallness of the vessels, indicate a deficiency in the quantity, as well as in the quality, of the blood.

56. Instances, however, may occur, in which the morbid colour of the surface is increased in the course of cachectic and malignant maladies, by the absorption of bile into the circulation, or by the accumulation in it of the elements or principles of which bile is formed, owing to torpor of the liver. Indeed, this latter cause of heightened discolouration of the surface, in the course of these maladies, is by no means rare; for the liver largely partakes of the depressed state of vital power characterising them. When malignant disease occurs either in the substance of the liver, or in parts near the capsule of GLISSON, it is generally associated with jaundice, which gradually deepens from a lemon hue to a dark or dusky green colour, the urine assuming a greenish brown tint, and the patient sinking from exhaustion and coma. This association has been well illustrated by the recent researches of Dr. BRIGHT, which have appeared since this article was written.

57. XI. OF THE DISTINCTIONS MADE BY AUTHORS.—Jaundice has been variously *distinguished* — into *Idiopathic* and *Symptomatic*; *continued* and *recurrent* or *periodical*; *febrile* and *non-febrile*; and into *Yellow* and *Black Jaundice* — *Icterus* and *Melasicterus*. It has been further distinguished into *Inflammatory*, *Plethoric*, and *Nervous*; into *sporadic*, *endemic*, and *epidemic*; into the *mild* or *benign*, and the *malignant* or *pernicious*. —Jaundice is generally *sporadic*; but it is *endemic* in some localities, particularly in those which are low, humid, and warm; and which abound in terrestrial exhalations, as in some situations in the South of Europe, and among Europeans residing in various parts within the tropics, particularly in the Eastern hemisphere. It has likewise been so prevalent at some periods, especially in autumn and early in winter, even in temperate countries, as to have been considered *epidemic*.

58. *The malignant* or *pernicious* form of jaundice, noticed by writers, sometimes occurs in warm climates, and in marshy districts in the South of Europe, particularly during autumn, when low remittent or bilious fevers are prevalent. It entirely depends upon a general or diffused inflammation, or inflammatory congestion, of the liver, or both of the liver and spleen, with retention of the biliary and other secretions, great depression of vital power, deep or dark green discolouration of the skin, very quick pulse and febrile disturbance, terminating rapidly, sometimes with intestinal hæmorrhage, and always with delirium and profound coma. This form of jaundice is not, however, confined to the climates and localities just specified; as I have been called, within a short time, to two cases in London, which presented all the characters of the most *pernicious* state of the disease, and which terminated fatally in four or five days.

59. *Idiopathic* or *primary jaundice* has been denied, first, by BOERHAAVE and STOLL, and subsequently by PINEL, LOUYER VILLERMAY, GRIMAUD, and others; whilst it has been contended for by numerous writers. The truth is, that the difference between idiopathic and symptomatic, particularly as relates to jaundice, is often merely verbal, and is in a great measure relative. In a very strict sense of these terms, jaundice is never a primary complaint; whilst it may frequently be viewed as such, if we consider it, with many other maladies, as constituting the principal, and one of

the earliest morbid conditions, which can be recognised by our senses. According to this more obvious mode of distinction, the occasional occurrence of idiopathic jaundice, as after mental emotions, cannot be disputed. The variety usually attributed to spasm of the ducts, but which I have considered as depending rather upon a change in the state of organic nervous influence and functions of the liver than upon spasm, may, conformably with this view, be considered idiopathic.

60. The *classifications* and *distinctions of jaundice* by nosologists and authors require no further notice. Indeed, they do not deserve the space they would occupy, especially as SAUVAGES adduces *forty-six species*, arranged, according to the various causes, pathological states, and associations, which the complaint presents. Even VILLENEUVE has divided it into *thirteen species*, several of which are subdivided into many *varieties*, which do not admit of any distinction in practice.

61. XII. PROGNOSIS.—The prognosis necessarily varies with the age, sex, temperament, and habit of the patient, and the pathological relations and complication of the disease. — *A*. It is generally more *favourable* in young, than in old, subjects; and in those, in whom the energies of the frame are sufficient to bring about a return to the healthy functions, than in persons of a broken-down constitution, and with disorganised viscera. If it occurs in females from plethora, occasioned by the suppression of the menses, previous to the climacteric period; if the health has not been previously much affected, — if the abdominal viscera betray no marked disease, — if the respiratory function is unembarrassed, the heart's action regular and natural, and the vital energies not materially depressed; if the colour does not progressively deepen; if it proceed from the sudden, and violent emotions of the mind, as anger, fright, &c., or from bodily pain; if it arise from articles of diet or of medicine, which have disagreed with the digestive organs; if it depend upon plethora of the portal system, without inflammation or abscess, or on the passage of calculi along the ducts, in persons not far advanced in age, nor greatly debilitated; if a repelled eruption or suppressed discharge return; if the alvine evacuations are not much changed from their natural colour, or when the biliary secretion reappears; if the discolouration originate in temporary obstruction or pressure on the ducts, as in pregnancy, distension of the duodenum or colon; if the epigastrium and hypochondria are not constantly painful, or tender upon pressure; and if the disease seems to proceed from the more temporary causes of obstruction in the duodenum, or from spasm; the prognosis may in general be *favourable*; — yet I have seen jaundice exist in these circumstances, and where there seemed no reason to infer an unfavourable issue, and coma has suddenly appeared, and quickly carried off the patient.

62. *B*. An *unfavourable* prognosis, on the other hand, or, if not strictly unfavourable, a very guarded opinion, should be given, when this affection occurs after the cessation of the menstrual periods, or in aged females, or when it is caused by debauchery and intemperate indulgences, particularly in spirituous liquors. If symptoms of organic lesion of the viscera attend it; if the epigastrium and hypochondria be tumid, tender, and constantly painful, with heat of the palms of the hands and soles of the feet; if the respiratory function be impeded, or the circulation through the heart be irregular or obstructed; if the energies of life be depressed; if chronic disease have preceded the discolouration of the surface; if the colour deepen, be of long standing, and particularly if it be of a dark green hue; if it take place from the continued operation of the same cause, as grief, anxiety, and the depressing emotions; if the urine be small in quantity, white, or albuminous, or very dark, turbid, thick or blackish; if there be indications of supervening dropsy; if a colliquative form of diarrhœa supervene, or very dark, grumous, or pitchy evacuations, or vomitings of a nearly similar matter; if the affection be of long duration, and particularly if it be associated with dropsical effusions; if hiccup, with tumefaction of the epigastrium and hypochondrium, or a tympanitic state of the abdomen, be present; if delirium, delirium tremens, mania, epilepsy, lethargy, coma, paralysis, convulsions, or apoplexy occur; if intestinal hæmorrhage, or hæmatemesis, take place; if the jaundice proceed from calculi in aged persons, or appear after repeated attacks of ague or remittent fevers, and from continued melancholia; if it be accompanied with great depression of the mental and physical powers; if marked cachexia, and great emaciation, be present, and especially if it be complicated with internal or external malignant disease, a very unfavourable prognosis should be given.

63. XIII. REMOTE and PROXIMATE CAUSES. — The chief causes have been stated in what has been advanced respecting the pathological relations of jaundice. — *a*. It is obvious, that the more *remote* causes are those which induce the alterations, of which the discolouration is a symptom. These are fully detailed above (§ 15.), and in the articles CONCRETIONS — BILIARY; DUODENUM; GALL BLADDER AND DUCTS; and LIVER — *Diseases of*. Those, which most frequently induce this complaint, are — habitual excitement of the liver, duodenum, and digestive organs generally, by too rich, too stimulating, or too much food, or by spirituous or intoxicating beverages; sudden and violent mental emotions; anxiety, or the depressing passions; high ranges of temperature, indolence, and full living; vicissitudes of temperature; the ingestion of cold fluids when the body is perspiring; miasmata or exhalations from the soil, especially in connection with humidity of the air; suppressed discharges and accustomed evacuations; interrupted circulation through the heart, occasioning congestion in the vena cava and hepatic vein; previous disease, particularly periodic fevers, &c.; whatever depresses the energies of life, and at the same time favours internal visceral obstruction; and the organic changes already noticed.—*b*. The *proximate* cause of jaundice may be stated to be the passage of the colouring or other principles of bile into the circulation, and the consequent discolouration of the skin and other tissues, heightened in some of the varieties by the accumulation in the blood of the elements of which bile is formed.

64. XIV. TREATMENT.—There are few diseases which require so much discrimination, as to the *indications* and *means of cure*, as jaundice. It

proceeds in different cases, as shown above, from so many different pathological states, and sometimes from so many combinations of them, that the utmost attention and practical acumen are necessary to ascertain the morbid conditions and peculiarities of the case, and to determine what is most efficacious in removing them. It is requisite not merely to guard against vascular excitement on the one hand, and vital depression on the other; but in many cases, also, to prevent or to remove both, as being the more immediate causes of the obstructed secretion or excretion of bile. In all cases, the states of general and local organic nervous power, as well as of general and local vascular fulness or action, must claim particular attention; and, in many, it will be found requisite to aid the former, whilst we diminish the latter. In any circumstances, it is very difficult to ascertain what are the effects of remedies upon the circulation and functions of the liver; for much of what has hitherto been said and written upon the subject, has been characterised by dogmatism, rather than by truth, — by vague assertion, unsupported by evidence. Some of the medicines, which have been supposed to excite the liver, probably operate by removing slight obstructions from the mouth of the common duct, by reducing vascular turgescence in the duodenum, and carrying off mucous collections; and others, which have been viewed as inert, as respects this organ, have as great influence upon its functions, as those whose effects have been considered specific. The operation of medicines in affections of the liver so much depends on the state of vital activity and of vascular action, on the extent to which biliary collections may have formed, and on the facilities to its excretion, that facts are rarely observed with that degree of precision in all these relations, which should entitle them to confidence, or to be made data for practical inferences.

65. i. *Jaundice from an exuberant Secretion of Bile*, there being no evidence of its obstruction, is not so frequent in this, as in miasmatous and warm climates. In these especially, the treatment must have due reference to the remote causes, and to the more immediate source of the biliary exuberance. In temperate climates, and in European constitutions, this state of the biliary function is connected with biliary remittent fever, and is most appropriately treated by the means most serviceable for the constitutional affection; but it sometimes continues, or returns, after the fever has disappeared. In these cases, as well as in those where it presents a more idiopathic character, there is every reason to infer the presence of active circulation in, or vascular determination to, the liver, probably with increased activity of the absorbent function. For them, moderate *local depletion* from the margins of the ribs, or from below the shoulder blades; *cooling diaphoretics*, especially the nitrate of potash, the solution of acetate of ammonia, or subcarbonate of soda, and spirits of nitric æther in camphor mixture; *emollients* and *demulcents*; soothing enemata and *diluents*; are the most efficacious means, particularly when the causes no longer exist, or when the patient is removed from the influence of miasmatous exhalations, or enjoys a dry and pure air.—The *diet* in these cases should be very spare, and consist of mucilaginous and farinaceous substances; animal food should be taken sparingly and cautiously during convalescence, and stimulating beverages entirely relinquished.

66. ii. *Jaundice from Inflammation of the Substance of the Liver* is more frequent than is generally supposed. It is often merely an exalted state of the former variety; the vascular disorder having advanced to such a pitch, as to obstruct the secretion or excretion of the bile, owing to the general turgescence of the vessels, and consequent pressure on the minuter bile ducts; and it is most frequently observed, when the internal structure of the organ is generally inflamed, or is the seat of one or of several abscesses. (See LIVER — *Inflammation of.*) When the attack is *slight*, and is attended by little pain, or by pain increasing slowly after pressure; and when there is little fever, the pulse being oppressed, rather than much accelerated; *local depletions* from the margins of the ribs, and from the anus, with the other means just advised (§ 65.), will generally remove all disorder. But when the bowels are costive, additional means will be required, especially *mercurials* with antimony; *saline medicines*, either alone, or with other *aperients*; a solution of sulphate of magnesia in camphor julep, with the solution of the acetate of ammonia, and spirits of nitric æther; the warm turpentine epithem applied over the epigastrium; the warm bath, &c.

67. In the more *acute cases*, particularly when there are much fever, intensely deep jaundice, very quick pulse, dry tongue, flushed countenance, and scanty, dark urine, the treatment should be most actively antiphlogistic. — General *bloodletting* ought to be early employed, and be followed by local depletion; by full doses of *calomel*, or of calomel with *James's powder*, camphor and opium; by *saline aperients*; by *antimonials* and saline *diaphoretics*; and by the rest of the means advised in the article on *Inflammation* and *Abscess* of this organ. In all such cases, the treatment should vary according to the history of the case, particularly in respect of previous disease of this viscus, and to the habits, age, and other circumstances of the patient. If the treatment be not active at the commencement, and in some instances where it has been both active and judicious, delirium and coma will supervene in four or five days, or even earlier, if vital power be exhausted, and if the discolouration be very deep. In this stage, treatment will seldom be of much avail. The propriety of then having recourse to depletion will entirely depend on the strength and frequency of the pulse, on the state of the hepatic regions, and on the means previously employed. In some, local depletions may still be resorted to; but, in all such, camphor with other mild restoratives will be appropriate. Calomel will seldom be of any use at this period, if it have been already liberally prescribed. If it have not been employed, it may be given with camphor. Some benefit may accrue from an occasional exhibition of a draught containing spirit of turpentine with, or without, castor oil; from the same substances administered in enemata, from the warm turpentine epithem applied over the epigastrium and hypochondria, and from a large blister on the nape. When jaundice is dependent upon abscess of the liver, the

treatment must be conducted as advised for this state of disease, in the article Liver.

68. iii. *Jaundice from Congestion of the Portal and Hepatic Veins* often requires very nearly the same treatment, as just recommended for the slighter states of the preceding variety (§ 66.). — *Local bloodletting* is generally sufficient; and, unless in cases where the congestion depends upon dilatation of the cavities of the heart, the application of leeches to the anus is preferable to cupping over the hypochondria. If the congestion is connected with a stoppage of the hæmorrhoidal flux, leeches are especially serviceable. When congestion is chiefly in the hepatic veins, the circulation through the heart and lungs is often interrupted, and the congestion soon extends to the portal system, to the mesenteric veins, and the digestive mucous surface; the early stage of jaundice being characterised by a bloated appearance of the face, sometimes with lividity of the lips, and a deficiency, merely, of the bile in the stools. In these cases, the treatment should be chiefly directed to the primary complaint, and be modified according to the evidence furnished of the cause of obstruction. (See Heart — *Organic Lesions of.*) — When *hæmorrhage* from the digestive or respiratory mucous surface occurs in this variety, as sometimes observed, *cupping* from the sternum, or leeches applied to the anus, will be of service. In many cases of this kind, the liver is more or less enlarged, owing to the prolonged congestion; and, although there can be but little expectation of a permanent restoration of this organ to its functions, whilst the obstruction to the circulation continues, deobstruent and saline *purgatives* will generally be useful, especially mercurials, the bitartrate of potash with the sub-borate of soda and confection of senna, the preparations of taraxacum with soda, and the hot turpentine epithem placed on the abdomen, &c. — *Dropsical effusion* sometimes takes place in the advanced course of this form of jaundice, and requires *diuretics*, in addition to the decided exhibition of the medicines just named. The internal and external use of the spirits of turpentine; the compound decoction of broom with the acetate of potash, or with carbonate of soda, and spirits of nitric æther; weak solutions of the hydriodate of potash, or the solution of potash; occasionally the more drastic or hydrogogue *purgatives*; and a course of deobstruent *mineral waters*, such as those of the Beulah Spa, of Cheltenham, Pullna, Seidschutz, &c.; will sometimes be of service.

69. iv. *Jaundice from Chronic Organic Lesions of the Liver* requires a treatment modified according to the history of the case, and the signs furnished by a careful examination of the hypochondria, and even of the lower regions of the thorax. If the patient have had attacks of acute or subacute hepatitis or dysentery, or is subject to chronic dysentery or diarrhœa, very probably the circulation through the extreme branches of the portal vein, and the passage of bile along the small ducts, are obstructed by a deposit of albuminous lymph from the inflamed vessels in the areolæ or reticulations of the connecting cellular tissue of the organ, and by the pressure on these vessels thereby occasioned. In cases of this kind, more or less enlargement of the liver may be detected, especially in those which are less chronic; although, in the more protracted, the liver may have regained its former size, or have become even smaller, its structure being dense, granulated, or otherwise changed. In these latter, the nutrition of the organ, as well as its functions, is impaired; and the deposits formed in the substance of the organ become organised, or partially identified with it, and perpetuate the obstruction. In this variety, particularly in the less prolonged instances of it, the *exciting causes* of the hepatic disorder should be avoided. — *Diet* and *regimen* will very much assist the treatment. Stimulating food and drink should be relinquished, and *deobstruents* and *alteratives* adopted. If any remains of inflammatory action still exist, *leeches* should be applied to the anus, or to the epigastrium. In any circumstances, Plummer's *pill* should be taken regularly at bedtime, either alone, or with a little *soap* and extract of *taraxacum* (F. 503. 511.), and the *bitartrate of potash*, with the *sub-borate of soda*, in any vehicle, or with other medicines, according to the state of the bowels (F. 89. 96. 98.).

70. If *evacuations of blood* from the bowels occur, the *hydrargyrum cum cretâ* with *ipecacuanha*, enemata containing *spirit of turpentine*, or an occasional draught with this substance and castor oil, or the *nitric* or *nitro-muriatic acids* in the simple infusion of roses, will be useful. In all cases, frequent *frictions* over the hypochondria and epigastrium with an oleaginous and deobstruent *liniment* (F. 297. 311.), or with this conjoined with the mercurial liniment, will be of essential benefit. This variety, like the preceding, is very apt to become complicated with *anasarca* or *ascites*, or with both. In this case, the decided use of *mercurials*, the more drastic and hydrogogue *purgatives*, the bitartrate of potash in large doses with borax, *diuretics*, and the other means noticed above, and advised for Dropsy, proceeding from disease of the liver, will be requisite. Assiduous frictions of the hypochondria and abdomen with *liniments*, particularly with these just mentioned, or with those containing the *iodide of potassium*, and a course of deobstruent and purgative *mineral waters* (§ 68.), will sometimes be of use.

71. v. *The more doubtful Source of Jaundice in Spasm of the Ducts* requires means which have a stricter reference to the remote causes, and to the symptoms peculiar to the case, than to the existence of spasm. A large proportion of the cases usually attributed to this state, most probably would have been found, upon a more accurate investigation, to belong either to congestion of the hepatic veins; or to calculi lodged in the ducts; or to obstruction of the mouth of the common duct, arising from the states of the duodenum; and they consequently would have required a similar treatment to these. The affection attributed to the ducts may have been almost entirely confined to the duodenum; the means found of service, as *calomel* alone, or with *opium*, saline or other *purgatives*, *anodynes*, *emetics*, &c., instead of acting upon the former, actually removing the disorder of the latter, or carrying off mucous sordes from its surface, or subduing vascular turgescence from around the opening of the common duct. — When there is any reason to suppose that the reputed spasm of the ducts is actually a paralysed state of the organic nervous influence of the liver and ducts, *restorative means* will then be required. The

chlorate of potash with carbonate of *soda*, gum *ammoniacum* with Castile soap, the nitric or *nitro-muriatic acids* given internally, or the nitro-muriatic acid lotion or bath, *frictions* with stimulating liniments on the hypochondria, the ammonical and mercurial *plaster* in this situation, and *blisters*, will be severally beneficial in cases of this kind, as well as in the immediately preceding variety, when the energies of life are much exhausted.

72. vi. *Jaundice from Obstruction of the Ducts* (§ 35.).—When the obstruction depends upon the *passage of calculi*, as evinced by the symptoms noticed above (§ 39.), and more fully described in the article, CONCRETIONS — BILIARY (§ 6.), the means fully detailed in that article (§ 14.) should be resorted to, especially full doses of *opium*, alone or with antimony, of *belladonna*, or of other narcotics; the *warm bath*, warm *fomentations*, or the *turpentine epithem* on the abdomen, &c. No advantage, but rather mischief, results from the exhibition of mercurials in this state of the disease. When the obstruction arises from *compression, inflammation, and obliteration of the ducts* (§ 38.), in some part of their course, or even near their entrance into the duodenum, as from malignant tubera or other organic changes in the liver, or in the vicinity of the capsule of GLISSON, and from the organic lesions of the duodenum and pancreas already noticed, Dr. BRIGHT considers that the evacuation of fatty matter in the stools is not infrequent, especially if the biliary obstruction is permanent. In these cases, jaundice assumes a dirty or dark green hue, and is but little benefited by treatment; emaciation, exhaustion, hæmorrhage from mucous surfaces, or coma, supervening, and terminating existence. Palliative means, however, should be employed, especially *opiates*, the *solution of potash*, or of the *iodide of potassium*, with extract of *conium* or *hyoscyamus*. The constitutional powers should be supported by mild tonics and gentle nourishment, and irritation of the stomach allayed by opiates and salines given in aromatic vehicles, or by other appropriate remedies.

73. vii. *The other States and Associations of Jaundice* require the same principles and means of cure as have been stated, according to the peculiarities of individual cases. — *a*. This especially obtains in respect of *green or black jaundice*, the most appropriate means for which have been just noticed (§ 46.); and in regard of *the complications and successions of jaundice* (§ 49.), which usually present one or other of the pathological states already considered, particularly under the first, second, and third varieties.

74. *b*. For *cachetic* or *pseudo-jaundice* (§ 45.), the remedies mentioned in the articles CACHEXY, CHLOROSIS, CANCER, FUNGOID DISEASE, &c., may be resorted to, when these or any other malignant malady resembles jaundice, owing to contamination of the circulating fluids, or is associated with it. In such cases of contamination, as well as in the very acute and febrile form of jaundice, denominated *malignant* or *pernicious* (§ 58.), the alkaline carbonates with camphor, solutions of the chlorate of potash, or of chlorinated soda; and the other means advised for the hepatic complications of *Typhoid* and *Putro-adynamic* FEVERS (§ 49.), will be most appropriate.

75. *c*. *Traumatic jaundice* (§ 52.) must be treated according to the symptoms evincing the existence of any of the pathological states and alterations above referred to (§ 26.), and conformably with the principles already stated.

76. *d*. *Infantile jaundice* (§ 53.) requires merely gentle aperients, especially the *hydrargyrum cum cretâ*, with dried *subcarbonate of soda* and *rhubarb*, with an occasional dose of *castor oil*.

77. viii. *Of various Remedies recommended by Authors for Jaundice*.—*A*. *Antiphlogistics* are advised by numerous writers in the treatment of jaundice. STOLL supposed that these means are more necessary in this complaint during winter or spring, than at the other seasons. — *a*. *General bloodletting* is directed by HIPPOCRATES, DE LA MOTTE, and others. ZACUTUS LUSITANUS also recommends it, but with the utmost caution. Dr. BRIGHT very properly limits it to the more acute or inflammatory cases. I have attempted above (§ 66. 67.), to point out the circumstances and varieties, in which it, as well as *local depletion*, should be practised; and have mentioned the situations where this latter may preferably be employed. — *b*. *Emetics* are prescribed by HIPPOCRATES, CÆLIUS AURELIANUS, HORSTIUS, LENTIN, HOFFMANN, BROCKLESBY, STOLL, and CONRADI. When diffused inflammation, or even congestion, of the liver is present, or when gall-stones are passing the ducts, they may be attended by some risk; but when inflammatory symptoms and pain are absent, and when the liver is not apparently enlarged or congested, they may be productive of benefit. — *c*. *Laxatives* and *purgatives* are much safer than emetics, and more generally appropriate. HIPPOCRATES, GALEN, FORESTUS, RULAND, &c., placed great dependence upon them. Much, however, depends upon the selection of them, appropriately to existing pathological states. SCHNEIDER prefers the combination of *senna* with *guaiacum*; OTTO, *aloes* with *soap*; LENTIN and HORN, *rhubarb* with *bitartrate of potash*; and the majority of recent writers in this country, *calomel* or *blue pill*, alone, or with other purgatives. I have found, after one or more doses of these last, that any of the former will be very serviceable, especially the bitartrate of potash in large doses, either with the sub-borate of soda (F. 790.), or with the confection of senna, or with this and guaiacum, according to the pathological states inferred to exist. Other purgatives will, nevertheless, be often equally beneficial; but, in the more inflammatory cases, the more cooling should be selected: and when a torpid state of the liver, or deficiency of vital action in it, is inferred, then the warmer, more stimulating, or stomachic aperients should be prescribed, and be aided by the other means advised for this state. — *d*. The *diet* should also be suited to the treatment; and where depletions and evacuations are required, it ought to be most spare, cooling, and chiefly mucilaginous, or consist of the mildest of the farinaceæ.

78. *B*. *Diaphoretics and sudorifics* are prescribed by CÆLIUS AURELIANUS, RIEDLIN, STOLL, RICHTER, &c.; and *antimonials* are the remedies belonging to this class, which are preferred by modern writers. When conjoined with other remedies, they are of much service; as with nitrate of potash, and the spirits of nitric æther, in the more inflammatory states, and with anodynes and opiates in some other circumstances.—The *warm bath*, the *vapour bath*, *fomentations*, and *warm poultices* may also be noticed under this

head, as being sometimes useful. A diaphoretic, as well as a deobstruent, effect is also produced by a combination of calomel with antimonials and opium, or of calomel, camphor, and opium; and is often of great benefit in the more imflammatory varieties, after general or local depletions.

79. *C. Deobstruents and alteratives* of various kinds are much insisted on by Lentin, Stoll, and most modern writers. Several of these, suitable to the more chronic cases of jaundice, are prescribed in the Appendix (F. 503. *et seq.*).— *a.* The deobstruent effects of *mercury* in this complaint are much confided in by Desault, Thomann, and most recent writers; but there is little agreement between them, as to the preparation which should be preferred, or as to the extent to which it should be pushed. Gibbon and others prefer *calomel,* and give it until it produces salivation. In the more chronic cases especially, I prefer Plummer's *pill* with *soap* and *taraxacum,* occasionally aided by *mercurial liniments,* or *plasters,* applied to the hypochondria. — *b.* Simple or medicated *soaps* are much praised by some authors, and particularly by Boyle, Stoerck, Ranoë and Quarin. They are often very useful, either alone, or with taraxacum, mild mercurials, oxgall, assafœtida, or with ammoniacum, or even with narcotics. The *alkaline subcarbonates,* and *solution of potash,* are also serviceable in similar combinations, and, as well as the soaps, are safe medicines in all states of the disease. — *c. Taraxacum,* in decoction or extract, has been much used in jaundice, since it was praised by Ranoë and Quarin; but it should be given in large doses, or be aided by other medicines, as the alkalies, soap, neutral salts, &c. I have given it with small doses of *colchicum,* and in other combinations. (F. 76, 77. 392.)—*d.* The *Solanum dulcamara* was recommended by Linnæus for jaundice, but it is rarely prescribed, although much used as an alterative in cutaneous eruptions depending upon, or connected with, biliary disorder. It may be advantageously given in decoction with taraxacum and the alkaline subcarbonates, or with the other alteratives already noticed (F. 59.), Plummer's pill being taken at night. — *e.* I am not aware that the preparations of *colchicum* have been recommended for this complaint by writers. I have, however, prescribed it in several cases with marked benefit, chiefly in conjunction with mild mercurials, or with soap, alkalies, &c., or with magnesia or neutral salts, according to circumstances. It should be given in small doses, be continued for a considerable time, and carefully watched. If there be much debility, or if it produce depression, it should be given with camphor, or the more tonic substances recommended for the complaint. It often increases the biliary secretion in the cases depending upon chronic inflammatory action, or enlargement of the liver; and promotes resolution of the former, and diminution of the latter, morbid state. — *f.* I have also given the preparations of *sarsaparilla* with advantage, in conjunction with the liquor potassæ.

80. *f.* The internal use of *nitric acid* was advised by Frank. It is likely to be useful in some of the more chronic states. The *nitro-muriatic acid* was praised by Scott, Annesley, and others. I have found it decidedly beneficial in some cases; but have, contrary to the usual mode, prescribed it internally as well as externally. It may be employed as a warm foot-bath, or as a lotion, applied warm or tepid, over the hypochondria and epigastrium. It is most serviceable in torpid states of the liver, and in the more chronic cases. It should not be employed when inflammatory action is present. — *g.* The *chlorate of potash,* or the *chlorinated soda,* will be sometimes useful in the circumstances or conditions of the disease in which these acids are indicated. The chlorate of potash may be advantageously conjoined with the carbonate of soda, or with other substances. — *h.* The preparations of *iodine* are sometimes also of service, in similar states of jaundice to those just alluded to, especially the *hydriodate* and the *iodides of mercury.* These may be given with *conium* or other narcotics, particularly where there is reason to infer the existence of chronic obstruction, or malignant disease of the liver, or of adjoining parts. — *i.* The *liquor potassæ* is also indicated in such cases, and in similar combinations.

81. *D. Diuretic deobstruents* are sometimes prescribed, but chiefly as adjuncts to aperients. They are noticed by Hippocrates and Riedlin. The *acetate of potash* (F. 841.) is the most useful of this class; but the *bitartrate* is equal to it as a diuretic, and even superior to it as a deobstruent in diseases of the liver, when given in large doses, so as to act upon the bowels, or when combined with the *sub-borate of soda* (F. 790.). Several of the foregoing medicines will be aided in their operation by emollient and mucilaginous diluents, as directed by Gilibert and others.

82. *E. Frictions* of the hypochondria and upper regions of the abdomen with stimulating and *deobstruent liniments* have received much less attention than they deserve. Indeed, they have hardly been noticed. When acute inflammatory action is not present, they will be found of much service. Several of those contained in the *Appendix* (F. 297. 311., &c.) may be prescribed either alone, or with *iodide of potassium,* or the *mercurial liniment.* Subsequently the ammoniacal and *mercurial plaster* may be kept applied to the side.

83. *F. Anodyne antispasmodics and narcotics* are directed by Vogler, Richter, Hufeland, Vogel, Brandis, and Conradi, chiefly on the supposition of jaundice being often a consequence of spasm; and ipecacuanha with opium is generally adopted by them. As this complaint often gradually disappears upon the cessation or removal of the remote cause which occasioned it, much of the benefit, that seems to follow these substances, probably depends upon this circumstance. When the disorder proceeds from the retention of a calculus in the ducts, they are probably useful in relaxing the parts, and thereby facilitating the excretion of it. — *Opiates* in full doses are prescribed by Wendelstatt, Vogler, Thomann, De Chave, &c.; and *belladonna,* by Greding. In the states just named, and when severe pain is present, the advantages derived from them are unquestionable, whether exhibited alone, or with calomel, or with alkaline subcarbonates, or with camphor and emollients.

84. *G.* Of *stimulating antispasmodics,* the *spirit of turpentine* is the most deserving of notice. It is recommended by Holst, Odier, and Durande. I have prescribed it with benefit in several varieties of the complaint, and in various modes, as already stated (§ 70.). — *Assafœtida* is mentioned by Herz: both it and *ammoniacum* are sometimes

of use in cases depending on torpid states of the liver, especially when conjoined with soap, alkalies, and other medicines already noticed. (See Form. 503—510. 891. 894.)—An infusion of the flowers of *arnica* was also prescribed by Plenciz and Stoll.

85. *H. Vegetable tonics and bitters* are directed by Riverius, conjoined with aperients; and are often of great service when thus exhibited, and when aided by the alkaline subcarbonates or neutral aperient salts.—The *absinthium* is recommended by Celsus, De Hayde, and Solenander; and *cinchona*, by Cammerarius, Fahner, and De Haen. This latter is prescribed with antimonials by Cornette; but it should be given with caution, as it is contra-indicated in the more inflammatory states of jaundice. I have had reason to believe it to have been even productive of the complaint, when exhibited freely in periodic fevers, before morbid secretions had been fully evacuated. The milder tonics and simple bitters are preferable to it in most cases, especially when they are prescribed as advised by Riverius, and when given during convalescence.

86. *I.* Of the *other means* advised by authors, there are few requiring particular notice. The watery extract of *Chelidonium*, and the extract of *Chicorium*, were recommended by Riverius, Lange, De Schullern, and others; the *Anagallis* with salines, bitters, and the ammonio-chloride of iron, by Stoll; the *Agrimonia*, by Hill; and the *Gramen caninus* and the *Berberis vulgaris* (F. 225.), by several writers. Inspissated *oxgall*, in as large doses as the stomach could bear, was prescribed by Stoll. *Blisters* on the hepatic region were directed by Bang; and *electricity*, by Hall and Darwin. The *mineral springs of Cheltenham*, of *Bath*, or of the *Beulah Spa*; the artificial mineral waters of *Seidschutz* and *Pullna*, or of *Ems*, *Eger*, and *Pyrmont*; are severally beneficial, when taken appropriately to the pathological states of the complaint. *Travelling* and *change of air* were much praised in jaundice by Celsus and Cælius Aurelianus, and in modern times by Gregory and others. Regular *exercise* on foot and on horseback is always of benefit, unless in cases depending upon inflammatory action.

87. The *Diet* and *Regimen* should be suited to the forms of the disease. — *Asses' milk* is advised by Hippocrates. *Common whey* and *goats' whey* are the best beverages that can be used during the attack. The drinks also prescribed under the head *Potus* in the *Appendix* (F. 588. *et seq.*), will generally be found useful. Upon the whole, the *diet* should be very nearly as advised in the article Concretions — Biliary (§ 18.).

ICHTHYOSIS. — Syn. Derived from ιχθυς, gen. υος, a fish. *Albaras nigra*, Avicenna. *Impetigo excorticativa ; Lepra Ichthyosis*, Sauvages. *Ichthyosis*, Willan. *Lepidosis Ichthyosis*, Young. *Lepidosis Ichthyosis*, Good. *Ichthyose*, Fr. *Fischschuppenaussatz*, Germ. *Ictiosi*, Ital. *Fish Skin, Fish Skin Disease.*

Classif. — 6. *Class*, Diseases of the Excernent Function ; 3. *Order*, Affecting the External Surface (*Good*). 2. *Order*, Scaly Diseases ; 4. *Genus* (*Willan*). IV. Class, IV. Order (*Author*).

1. Defin. — *Morbid enlargement of the papillæ of the skin, and thickening of the lamellæ of the epidermis, either in parts, or over the general surface, presenting irregular compartments, and resembling in many cases the scales of fish.*

2. *Ichthyosis* is defined by Willan and Bateman, to be a papillary, indurated, and horny condition of the skin, to a greater or less extent. It has been placed by them among squamous diseases, but more recent writers have justly contended that it does not belong to this order. It consists of a morbid enlargement and elongation of the papillæ, and a thickening of the epidermis. Horny peduncles are thus formed, which spread so as to acquire broad irregular tops, and, undergoing partial exfoliation, sometimes resemble the scales of a fish.

3. This affection is *general* or *local*, and *hereditary* or *accidental*. When it is hereditary, it either is congenital, or it does not appear until some months after birth. The local form is most frequently accidental, the more general affection is commonly congenital or hereditary. The states of the complaint have been differently divided, and even described, by writers. The division and description of Dr. A. T. Thomson, are altogether incorrect, inasmuch as he confounds, as M. Rayer has shown, a disease of the cutaneous follicles with this affection, and mixes up a description of both, under the denomination of *Fortuitous Ichthyosis*.

4. I. Description. — i. *Hereditary Ichthyosis* is commonly general, affecting those places chiefly in which the skin is naturally thick and the epidermis rough, and being entirely wanting on the prepuce, eyelids, groins, axillæ, and on the palms of the hands and soles of the feet. When the disease is *congenital*, it is usually but little apparent; but the skin, instead of being soft and smooth, is sallow, dry, and shagreen-like. In the course of the two first months, the cuticle becomes, particularly in places, rough, thick, and of a greyish or sallow hue. It may remain in this state for years, or even during life, without proceeding further; but the alteration may increase until it is very remarkable.—Ichthyosis sometimes does not appear until several months after birth. It is then often developed more rapidly, until the epidermis is divided into small irregular compartments, resembling that covering the legs of fowls, or the scales of serpents, the "*Ichthyose nacrée serpentine*" of Alibert.

5. Hereditary ichthyosis is sometimes limited in extent, and is confined chiefly to the extremities. It is then still more remarkably developed, and assumes the appearance of a thick epidermic layer, or of the bark of certain trees. In these cases, as in the foregoing, the epidermis is composed of a number of small compartments of irregular shapes, which are not imbricated, are from two to three lines in diameter, but are often broad in proportion as they are thin. The morbid surface is generally greyish or sallow; sometimes of a brownish hue; but, in a few cases, it is shining or opalescent. It is so rough, that it feels like shagreen, or like the surface of a file, when the hand is passed over it, — "*Ichthyose nacrée cyprine*" of Alibert. — In these states of the complaint, the epidermis is chiefly altered; and the scales, excepting the largest, which adhere strongly, may be removed without causing much uneasiness. But, however detached, they are soon reproduced.

6. ii. *Papillary Ichthyosis*, or that in which there is chiefly a *remarkable elongation of the papillæ* of the skin, is a very rare variety. The first case of this kind, which was minutely described, was that of a native of Suffolk, who exhibited himself, in 1710, under the name of the *porcupine man*. More recently a family of the name of Lambert, affected with this variety, were described by Geoffroy St. Hillaire, and others. About 1830, I examined a very remarkable case, which was seen by many of the medical men of the metropolis. In all these instances, the complaint was confined to the males of a family. The brothers Lambert could trace it back through five generations, all of which were affected with it. The alteration of the skin appears to have been the same in all the cases, and identical with that which I examined. The *papillæ* were remarkably hypertrophied and elongated, over nearly the whole of the cutaneous surface, excepting the prepuce, axillæ, groins, eyelids, soles of the feet, and palms of the hands. Over the rest of the body, the elongated papillæ presented the form of short spines closely pressed together. They were whitish or greyish when separated, but blackish or brown on their exposed surface: and so hard and elastic, that they produced a noise when the hand was passed quickly over them. These productions have generally exuded a reddish brown serum, when divided close to their bases, and have soon been reproduced. They could not be removed without pain.

7. iii. *Accidental and Local Ichthyosis* is a very distinct form of the disease from the foregoing, and is generally produced by pressure. It sometimes occurs on the lower and anterior parts of the thighs of shoemakers; and in other parts, where pressure is made, in various employments. It thus resembles corns in its mode of production.

8. In *the several forms of ichthyosis*, the morbid

cuticle is generally thrown off in summer, or at other seasons, but it is soon after reproduced. RAYER states that the skin, divested of its squamæ, shows no appearance of inflammation; and that its colour is natural, only the shallow furrows on the surface are more remarkable than usual. The cutaneous perspiration and follicular secretion are suppressed. The complaint is not attended by pruritus, or by any other morbid sensation: the general health is unaffected by it. When it is general, copious perspirations take place from the soles of the feet, palms of the hands, and other parts above stated to be free from it. The pulmonary exhalation and urine are probably increased, in proportion to the diminution of the cutaneous exhalation. RAYER thinks, that persons affected with ichthyosis are liable to be attacked with acute inflammation of the skin, which throws off the morbid cuticle; but the original complaint is soon afterwards reproduced.

9. iv. *The Anatomical Changes* constituting ichthyosis have been described by TILESIUS, BUNIVA, and RAYER. The small compartments, into which the epidermic layer is divided, do not overlap each other like the scales of fish: hence the term ichthyosis is inappropriate. These layers, according to BUNIVA, consist chiefly of gelatine, hardened by phosphate and carbonate of lime. M. DELVAUX states, that they contain also traces of iron and of silica. They present the same chemical constituents as the hair, nails, &c. The lines or furrows of the surface of the corion are more distinct, and the papillary eminences more decided, in this complaint, than in the natural state. TILESIUS found the cutaneous follicles obstructed, and full of a thick substance, in *the papillary variety* (§ 6.); and in the *squamous varieties* examined by RAYER, these follicles were but little apparent, or imperceptible. Dr. MARTIN observed the hair and hair-bulbs remarkably enlarged; and the corion is usually thicker, harder, and denser than natural. Ichthyosis appears to be unconnected with any internal disease.

10. II. DIAGNOSIS.—This affection is improperly classed by WILLAN and BATEMAN with squamous diseases, for it is entirely independent of inflammatory action. True ichthyosis always commences in a few months after birth, if it have not already existed; for the local variety can hardly be considered as connected with it, otherwise than in external appearance, and in the absence of inflammation. — In *lepra*, *psoriasis*, and *pityriasis*, the formation of scales is constantly preceded by redness of the skin: *lichen* is attended by severe pruritus, and preceded by the eruption of papulæ; and the scaly condition of *chronic eczema* is quite distinct from local ichthyosis. Ichthyosis, on the contrary, is attended neither by heat nor by pruritus, and is perfectly free from every inflammatory symptom. The *horny* or *warty productions* on the skin, — the former of which has been classed by WILLAN and BATEMAN with this complaint, — are entirely different from it, not only as to the form of the morbid formation, but also as to the extent of surface affected; these productions being limited to one or more points of the cutaneous surface.

11. The *ichthyosis of the face*, noticed by Dr. BATEMAN and Dr. A. T. THOMSON, has been more correctly described by M. RAYER, who has shown it to consist of a *sebaceous deposit* from diseased follicles. I have met with one instance of this affection, extending over, and on both sides of, the nose. It is always associated with inflammatory action, in its developed state. The following is the description of it by RAYER: — "The part of the integument affected, becomes, at first, unctuous or oily: the secretion of the sebaceous follicles then increases; the fluid thrown out upon the surface acquires additional consistency, and finally forms a kind of *squamous crust or layer*, of greater or smaller extent. Soft at first, and adhering but slightly, it by and by acquires hardness, and then cannot be removed without very considerable pain. The skin under this sebaceous deposit is of a vivid red; the orifices of the follicles appear dilated, and sometimes distended with concrete sebaceous matter."

12. III. CAUSES.—M. RAYER considers general ichthyosis to be a not infrequent disease. He has seen upwards of forty cases of it. It is known to be transmitted through several generations, and only to the male offspring. The whole of the male children of the same father and mother, who were themselves free from it, have been affected with ichthyosis. This was the case with two brothers, one of whom was in the Hospital "*De là Charité*," in 1827. This disease is very seldom produced accidentally long after birth. Neither climate, nor temperature, nor mode of life, exercises any influence in causing it. Some have ascribed it to moral affections of the mother during pregnancy; but this is extremely problematical. That it may be congenital, without the parents having been affected by it, is shown by a fact stated by RAYER: — He was consulted respecting three little boys who had it congenitally. Both parents were quite healthy and well formed, and the mother had never experienced disquietude nor alarm during these three pregnancies. It is very rarely observed in females.

13. IV. PROGNOSIS.—Hereditary, or congenital ichthyosis, frequently disappears for a time in consequence of acute inflammation of the skin; but a person affected with it can hardly be considered as likely to be permanently cured of it. Accidental and local ichthyosis, however, often yields to treatment.

14. V. TREATMENT.—i. *Hereditary ichthyosis* of considerable extent has rarely been permanently cured. M. RAYER states, that he has not succeeded in a single case. Happily this alteration of the skin is unattended by internal disorder, and is thus, comparatively, of little consequence. Emollient applications long continued, gentle frictions, mucilaginous and soothing fomentations, tepid baths frequently repeated, or alternated with the watery vapour, or the alkaline warm bath, have been severally employed in clearing the skin from the scales covering it, or in preparing it for the application of other remedies. WILLAN and BATEMAN prescribed without benefit various plasters, stimulating lotions, and other topical applications. Mr. COULSON resorted to a wash containing corrosive sublimate, in a boy, who was under his care; and subsequently, a liniment consisting of half an ounce of the ointment of nitrate of mercury and an ounce of olive oil, which was applied twice in the day. The scales soon disappeared, but the brown colour of the skin still continued. WILLAN recommends tar and pitch for this complaint; and gave as much as half an ounce, or even an ounce, daily, for some months:

and Bateman adopted the same treatment, with advantage both to the local affection and to the general health. Dr. Elliotson, for one of two brothers affected with ichthyosis, prescribed a warm bath every day, and desired the patient to anoint himself, on coming out of it, with oil; gentle friction of the surface, with sweet oil being employed twice a day besides. *Pitch* was also given internally, and increased gradually until ten scruples were taken three times in the day. The patient was clothed in flannel; was advised never to wipe the surface of his body after having anointed himself; and was directed to wear the same flannel shirt, drawers, and stockings, so that his skin was kept impregnated with oil. In about six or seven weeks the disease disappeared, the skin being soft and supple. The pitch produced no effect on the organs of digestion; and it neither was mixed with, nor had altered the smell of, the evacuations. Dr. Elliotson refers to two instances of the disease having been cured by Dr. Willan, by the use of pitch taken to the extent of an ounce daily. In Dr. Elliotson's case, no benefit was derived from the warm bath, as it produced smarting of the surface after the removal of the thickened cuticle; but the use of the oil probably accelerated the cure. The arsenical solution has also been tried, but with either very little or no benefit.

15. ii. For *local or accidental ichthyosis*, flying blisters, or topical stimulants, have been directed. Gentle frictions with a flannel cloth after coming out of a simple or sulphureous tepid water bath, and the sulphureous fumigating baths, aided by active exercise, have been found most serviceable in this form of the complaint. Mr. Plumbe succeeded in two cases, in removing this alteration of the skin, which was limited to the legs, by strapping the parts tightly with adhesive plaster, and applying a roller kept constantly moist with cold water. The straps were removed every fourth or fifth day. On the whole, this affection has been found to be very little under the control of medicine; and, notwithstanding the most active treatment has been adopted, the disorder has been known to continue for several years, with occasional variations.

16. iii. The *affection of the sebaceous follicles* of the face, mistaken by Dr. A. T. Thomson for ichthyosis, was successfully treated, by the decoction of the dock root, or the *Rumex obtusifolius*. It is prepared from one ounce of the sliced recent root, boiled in two pints of water down to one pint. The dose is a wine glass full three times in the day. It may be taken alone, or with the arsenical solution; if it should purge too briskly, a few drops of the tincture of opium may be added to each dose.

IMPETIGINOUS AFFECTIONS. — Syn. *Impetigo* (from *impeto*, I attack or infest), Celsus, Pliny. Λειχην αλφος, Galen. *Lepra Squamosa*, Auct. var.; *Herpes*, *Phlyctæna*, *Lichen*, &c., Auct. *Phlysis Impetigo*, Young. *Ecpyesis Impetigo*, Good. *Dartre*, *Dartre crouteuse*, Fr. *Zittermal*, *Ringwarm*, Germ. *Impetigine*, Ital. *Tetter*, *Humid or Running Tetter.*

Classif. — 3. *Class*; 3. *Order* (*Cullen*). 6. *Class*; 3. *Order* (*Good*). 5. *Order*, Pustular Eruptions (*Willan*). III. Class, I. Order (*Author*).

1. Defin. — *An eruption of one or more crops of small, yellow, itching pustules, disseminated or collected in clusters, the contents of which dry up in a short time, and assume the form of yellowish, rough, or prominent incrustations; generally unaccompanied by fever, and not contagious.*

2. I. Description. — Impetigo may attack every part of the body. It may be simple or complicated. Willan, Bateman, and Biett enumerate five species of the disease. I agree, however, with Dr. A. T. Thomson, in limiting them to two; three of those proposed by Willan being merely varieties of simple impetigo. The first species, or simple impetigo, according to this view, is unattended with fever, and comprises the figured, scattered, and scabid varieties. The second, or complicated, or erysepelatous species is attended with fever, owing, probably, to the extension of the inflammatory action to the more deeply seated integumental tissues.

3. i. *Simple Impetigo* — *Impetigo simplex* — usually occurs without any premonitory symptoms or derangement of health. It is met with most frequently in children at the period of dentition, in young persons of either sex, and in those of a sanguineous and lymphatic temperament, with a fine susceptible skin and florid complexion. It most commonly appears in the spring, at which season several have been periodically attacked by it during many successive years. This species occurs principally under two varieties. The pustules may be collected in circular or oval groups, occupying a surface of greater or less extent, but pretty exactly circumscribed: this variety constitutes the *Impetigo figurata* of Willan. Or the pustules may be scattered far apart, assuming no particular form, but disseminated over a surface of variable extent: this variety has been called *Impetigo sparsa*. To these a third division has been added, by the name of *Impetigo scabida*, but this is merely a more severe form of *impetigo sparsa*. Many intermediate degrees exist between these varieties; but the characters they present are

sufficiently distinct to give scope to the general study of the disease. At the same time each variety may be acute or chronic, according as it consists of a single crop, or of successive eruptions, of pustules.

4. *A. Impetigo figurata — Dartre crustacée flavescente* of M. ALIBERT — is the most common of these affections. It may occur in any part of the body, — on the neck, trunk, and extremities, particularly the hands; but it generally occupies the face, appearing most frequently on the middle of the cheeks, from whence it extends, in a circular or oval direction, over a considerable extent of surface. Sometimes it is confined to the eyelids, when it is commonly complicated with ophthalmia; and occasionally it appears on the chin, the ala nasi, and immediately below the margin of the septum of the nose. Although this variety usually occurs without very manifest disease of the general system, yet it not unfrequently follows anxiety or other depressing affections of the mind. In this case it is ushered in by a feeling of lassitude, by disorder of the digestive functions, by weakness and uneasiness, accompanied by pain in the epigastric region, and sometimes by cephalalgia. The eruption, as it first appears on the face, commences by one or more small, red, and very superficial blotches, which itch considerably, and gradually enlarge, becoming covered with small, yellowish, psydracious pustules, placed so close to each other as to be almost confluent, and surrounded by a red inflamed border. The pustules are but slightly elevated, and are the seat and source of much heat and stinging pain. These clusters, which are usually of a circular or oval form, and of various dimensions, may continue isolated, or extend still further by the development of fresh pustules at their circumference; and the eruption may be so extensive, that both cheeks, and even the whole chin, may be covered with it at once. The pustules, however, do not remain long in this state; but in the course of thirty-six or forty-eight hours, or at most three days, they burst, and discharge an ichorous fluid, which dries quickly and is converted into a yellowish crust of greater or less thickness, very friable, slightly furrowed, semitransparent, and resembling portions of candied honey, or the concrete gummy exudations on a cherry-tree. At the same time the discharge continues under these crusts, thereby increasing their thickness, and causing them to extend considerably beyond the limits of the original pustules; and it is usually at this stage of the disease that the patient is seen by the practitioner. The skin in the circumference of these incrustations is of a red colour; and if the scabs fall or are rubbed off, the integuments under them appear likewise red and excoriated, exhibiting at the same time minute pores, from which a purulent discharge exudes, which greatly augments the heat and smarting. Towards the edges of these diseased patches may be still seen some unbroken psydracious pustules, and others over which the liquid has flowed when it is scarcely coagulated. If the disease be of great extent, the features can hardly be recognised.

5. *Impetigo figurata* continues in its crustaceous state from two to four weeks, when it is not protracted by successive eruptions: the itching and heat then abate, as well as the morbid secretion; the incrustations become drier, and fall off irregularly, leaving one or more red spots or marks, which remain visible for more than a month. The cuticle at the same time is so thin, as to be liable to excoriation from the slightest friction, and a very trifling exciting cause often brings back the disease. More frequently, however, the ichorous discharge is reproduced, accompanied with fresh crops of psydracious pustules; the eruption is repeatedly renewed after running its usual course, and thus continues for many months, sometimes for years. In this manner it becomes a chronic disease, although the successive inflammations keep it always in an active state. In these cases the inflammation does not spread superficially, but penetrates the whole thickness of the skin, and sometimes affects the subcutaneous cellular tissue. When the disease yields either spontaneously, or to medical treatment, the amendment commences in the centre of the patches; and even when this occurs, not infrequently the edges retain their diseased character, and fresh pustules are produced: these, however, as the treatment proves successful, also gradually disappear; and the skin regains its natural colour slowly in these parts.

6. *Impetigo figurata* may appear on the limbs; and even on the body. When it affects the lower extremities, the patches are usually large, and of an irregular oval, whereas they are smaller and rounder on the upper limbs. Sometimes the patches enlarge by successive marginal crops: this has been observed on the legs, which have thus been gradually covered from above the knee to the ankle. The disease often becomes chronic, and the time of its duration varies. In such cases, we do not observe successive and abundant crops of pustules, or these large inflamed patches, but merely a few occasionally. Frequently, however, no pustules are found; but the peculiar form of the patches and crusts, with the partial eruption from time to time, suffice to characterise it. In some instances the pustules are intermixed with transparent vesicles, as in some of the varieties of *herpes*. When this intermixture occurs, the disease is much more troublesome from the extreme irritation, itching, smarting, and heat, which accompany it, and is much more difficult of cure. When these vesicles break, they discharge a fluid much more acrimonious than that of the pustules, which, wherever it touches the sound skin, produces a vesicular inflammation and a pustular eruption. This variety of the affection appears principally on the hand, about the metacarpal bones, or on the wrist. The vesicles appear in slow succession at a little distance from each other and from the pustules; when broken, they are little disposed to heal; and the cuticle ultimately becomes thickened and inflamed, and covered with the rising eruptions, small humid ulcers, and chaps or fissures. The sensation of burning and intense itching is extremely distressing, especially on the first rising of the vesicles; and every remedial application, which is employed, becomes a source of irritation, and increases the evil.

7. *B. Impetigo sparsa* differs from the preceding variety merely in the irregular and scattered distribution of the eruption. Its nature and progress are the same; but, instead of being arranged in circumscribed groups, its pustules are dispersed without any regular order over the extremities,

neck, face, shoulders, and external ears. This variety is most prevalent in autumn, continuing obstinately throughout the winter, and disappearing only at the approach of summer. It has a greater tendency to pass into the chronic state than the last variety. Although it may develop itself on any part of the body, yet it affects more particularly the extremities, manifesting an especial predilection for the legs, and in that situation becoming extremely troublesome and obstinate. Sometimes it confines itself to one spot alone; at others, it covers a whole limb, or even more than one at the same time.

8. The pustules in *impetigo sparsa* are developed in the same manner as in *impetigo figurata ;* but here, instead of being collected together, they are scattered irregularly over the diseased surface, and accompanied with insupportable itching. The incrustations also, which follow the bursting of the pustules, are thicker and more friable, and not formed into so large plates as in *impetigo figurata :* the attendant inflammation is, however, more extensive ; and as they fall off and disappear, the surface of the limb becomes studded with ulcerations and fissures. Œdema is not an infrequent attendant or consequence of this variety of the disease.

9. In some cases, and especially in persons of advanced age, with enfeebled constitutions, the crusts attain a great thickness: they are of a yellowish brown colour, variously divided by deep fissures. They have been compared to the bark of a tree by Willan, who calls this variety *Impetigo scabida.* It is, however, nothing more than a severer form of the last variety. Sometimes these crusts cover a whole limb, till it is cased with them, the motion of it becoming both difficult and painful; at the same time considerable heat and a tormenting itching exist. After a while, these crusts split; and, when a portion of them is detached, a copious discharge exudes from the excoriated surface, quickly concretes, and fills up the vacuity. When this variety affects the lower extremities, and is very severe, it sometimes occasions œdematous infiltration and ulceration, and even extends to the toes and secreting matrices of the nails — *Onychia Impetiginodes.* The œdema and ulceration commonly appear about the ankles, particularly in aged, weakly, or broken-down constitutions. The ulcers are uneven ; and either discharge a sero-purulent fluid, or are covered by yellowish crusts ; their edges being irregular, purplish, or livid, and often crowned with small sanguineolent pustules. When this variety occurs in the upper extremities, it does not differ from that already described, but it is much less severe, and its chronic form more rarely associated with œdema and ulceration, than that observed in the lower extremities. Acute *impetigo sparsa* of the face usually presents greenish yellow incrustations, dispersed over the cheeks or adhering to the beard in the adult. In children, the inflammation often extends to the nose, which swells, and is sometimes plugged up ; the disease then frequently becoming chronic.

10. *C. Impetigo Favosa.*—This variety is merely impetigo sparsa affecting the *neck, ears,* and *hairy scalp* — the *Porrigo favosa* of Willan, and *Tinea granulata* of Alibert — especially of children, and occasionally of adults. It occurs most frequently in the back parts of the head, but the entire scalp may be implicated; and it appears as yellowish white pustules, irregularly scattered over the hairy scalp, and attended by inflammation and pruritus, their centres being traversed by hairs. In from two to four days, the pustules pour out a fluid, which agglutinates the hair, and dries into small brownish or greyish, rough, and irregular crusts or masses like candied sugar. These become friable and detached from the surface, but adhere to the hair, which often seems filled with them ; a faint, sickly, or unpleasant smell being exhaled from the head, when cleanliness is neglected. *Pediculi* multiply rapidly, and swarm in the hair, which is not lost, but is often agglutinated or matted by the discharge.—Impetigo of the hairy scalp is not contagious, and does not implicate the piliferous bulbs, like *favus* or true *porrigo.* It seldom lasts longer than some months ; and it commonly is removed in the course of a few weeks, with proper treatment. When it becomes chronic, the inflammation often extends to the cellular tissue underneath, giving rise to small circumscribed abscesses. The lymphatic glands of the neck are frequently enlarged and painful.—Rayer and Green consider that this affection of the scalp is strictly a form of *Impetigo sparsa,* and not a variety of the disease, to which Willan has applied the term *Porrigo;* and I am of the same opinion.

11. ii. *Complicated Impetigo.* — *A. Impetigo Eczematosa.* — Impetigo is sometimes associated with *Eczema—Eczema Impetiginodes.* (See art. Eczema, § 5.) The eruption so frequent in infants during suckling and teething, commonly called *Crusta Lactea,* or *Milk Scall,* is evidently an association of this kind, chiefly affecting the face, and extending partially to the scalp ; the characters of eczema predominating in some infants, and those of impetigo in others. Occasionally it assumes nearly the appearance of impetigo figurata. It has been variously arranged by writers on diseases of the skin, who have, even to the present day, been more desirous to point out, and even to feign, distinctions, than to trace the changes which these diseases undergo, and the connections which subsist between them, or to show how frequently the one runs into the other ; and has been termed *Impetigo larvalis, Impetigo mucosa, Tinea lactea* (Sauvages), *Tinea benigna, Tinea muciflua* (Alibert), *Porrigo lactea, Porrigo larvalis* (Willan, Bateman), *Lactumen, Eczema lactea,* &c., according as it was supposed to be allied to *Impetigo, Porrigo,* or *Eczema.* This of itself is sufficient to show the very intimate relation of these affections to each other, and to point out the necessity of considering them in their natural conditions, and in connection with their particular seats, and with the states of vital action ; and not merely with reference to certain artificial distinctions, which often cannot be ascertained, and which sometimes do not exist. The differences between *vesicles* and *pustules,* so much insisted on in the classifications usually adopted at the present time, often do not exist, or exist not in such a manner as to become available to the practitioner. These, and numerous others, so implicitly received as matters of belief, may be useful, as a part of the craft of the adept; but they are of very minor importance in the estimation of the truly philosophic observer, and are valued by him for just as much as they may be worth, in the particular cases in which

they are manifest. An eruption may be vesicular to-day, and pustular to-morrow; or, in other words, the former, owing to changes in the vital actions of the part affected, and in the morbid secretion, may pass into the latter; or both kinds of eruption may be coexistent or coëtaneous, either in the same, or in different, situations of the same case. Instances will also occur, in which the most acute observers will be puzzled to determine whether the primary eruption is vesicular or pustular; for it may be intermediate as respects the appearances both of the contained fluid, and of the containing and surrounding tissues. To whatever genus this eruption may be referred, — whether it be dignified in being described as a genus of itself, or be viewed as merely a species, or be debased to the rank merely of a mongrel variety, — it is consolatory to know, that, in its intenser states and more extended forms, as well as in slighter grades, and however great the attendant pruritus and pain may be, or however deep the chaps or fissures may seem, no permanent marks or cicatrices are produced by them.

12. *B. Impetigo Erysipelatodes* is easily distinguished, by presenting, at its commencement, the ordinary symptoms of erysipelas. The other varieties of the eruption are in general unattended by any febrile disturbance, although the digestive organs may be more or less disordered. But this is ushered in by decided symptoms of constitutional commotion. Its premonitory stage is characterised by perturbation of the system, fever, much burning and smarting heat, an œdematous state of the eyelids, and a redness and puffy swelling on the upper part of the face. This state of things continues for two or three days; when, on running the finger over it, the surface, instead of the smoothness of erysipelas, is found to exhibit a slight inequality; and on minute examination it seems papular. In a day or two more it is covered with numerous psydracious pustules, which first appear below the eyes, but soon cover the greater part of the face, and sometimes extend to the neck and breast. The itching, smarting, and sense of heat, which accompany these pustules, are very distressing. When they break, a hot acrid fluid exudes, which irritates, and often excoriates, the sound surface on which it flows. The face remains in this painful condition for ten or fourteen days, when the discharge diminishes, and concretes into thin yellowish scabs, in the interstices between which, fresh pustules arise at intervals with renewed heat and pain, and run the same course as the former. The disease may continue thus severe and troublesome for two or three months. The period of its duration, however, is uncertain; and when it disappears, it leaves the cuticle in the same dry, red, and brittle state, which characterises the departure of the other varieties of impetigo. During the progress of this disease, the health of the patient is not very much disordered, and the constitutional disturbance is much less than in erysipelas. This form of the disease is occasionally confounded with *eczema impetiginodes*. In the advanced stage, however, the distinction is easily recognised.

13. Besides the above varieties of *impetigo*, Willan and Bateman mention another, under the title of *Impetigo rodens*. It is, however, of very rare occurrence, and cannot with propriety be called an impetiginous disease, being more of a malignant ulcer, complicated with psydracia. It is said to be uniformly fatal, and to have been benefited by no remedies, either external or internal, which have been employed for its relief.

14. II. Diagnosis. — The varieties of impetigo are liable to be confounded with other pustular eruptions, especially *porrigo*, *ecthyma*, and *scabies*, and with *eczema;* but a careful inspection of the pustules and of the incrustations, as either may present themselves, will show the differences between them. — *a*. The clusters of *impetigo* are distinguished from the circles of *porrigo*, in not continuing to pour forth a purulent and glutinous discharge, but, after the first eruption, an ichorous humour; and in not forming those thick soft and copious scabs, which characterise the latter disease. The pustules of impetigo discharge, while those of porrigo, seated more deeply, are quickly changed into dry, yellowish-coloured, cup-shaped scabs. The crusts of the former are brown, or of a dull grey, and not broad, thick, nor continuous, as in *porrigo scutulata*. Impetigo of the hairy scalp is not likely to be mistaken for *porrigo lupinosa:* it does not implicate the piliferous bulbs, like this and the other varieties of porrigo. It is distinguished, however, with greater difficulty from *eczema impetiginodes* affecting this part, the principal difference being in the appearance of the incrustations; but, as already insisted on, these latter are very nearly related eruptions. — *b*. The diagnosis between *impetigo* and *scabies* depends on the distribution of the eruption in patches; the copious exudation of ichor; and the reddened, rough, and fissured cuticle; and the heat and smarting, which accompany the itching, in the former. In the strictly purulent scabies, the pustules rise to a much greater elevation and magnitude, than in this complaint, and are filled with a thick, yellow pus, and are more inflamed around their base. Porrigo and scabies are contagious; but none of the varieties of impetigo possesses this property. — *c*. In its more advanced stage, impetigo may be mistaken for *psoriasis* or *lepra;* but, in these, there are no laminated concretions of ichorous matter or lymph, the squamæ consisting of exfoliations of morbid cuticle. These scaly diseases emit no fluid; and the existence of pustules and of a discharge, however slight, are sufficient to determine the impetiginous eruption. — *d*. The pustules of *psycosis* are larger, and not so yellow, and are more isolated and more prominent, than those of impetigo; which are always much crowded, and secrete abundantly. The scabs of the former are drier and of a deeper colour than the crusts of the latter; and are reproduced only after a fresh eruption of pustules. The crusts in impetigo are greenish yellow, thick, semitransparent and reproduced without any renewal of the pustules. In psycosis, also, the pustules do not break till the fifth, sixth, or seventh day; whilst in impetigo they burst on the third or fourth. Moreover, tubercles and indurations are observed in the former, but not in the latter. — *e*. Impetigo is more likely to be confounded with *syphilitic eruptions* on the face; but the peculiar character of venereal desquamations, or the firmly adherent scabs, concealing ulcers and leaving indelible cicatrices, sufficiently distinguish the latter from the former. Some of the forms of eczema may be mistaken for impetigo, but the diagnosis has been fully stated in the article Eczema (§ 13.). The

most superficial observation will detect the very marked difference between *acne rosacea* and this complaint. Mr. Dendy states that the internal use of the deuto-ioduret of mercury often produces vesicles, followed by yellow or yellowish green scaly crusts, which may be easily mistaken for those of impetigo and porrigo.

15. III. Prognosis.—This is more favourable in impetigo than in *lichen*, *lepra*, *psoriasis*, *eczema*, and many other cutaneous eruptions. In whatever part of the body the disease, in its *acute state*, be situated, it generally yields to medicine in two or three weeks. Its duration in the *chronic form* cannot be stated with precision; as this necessarily depends on the constitution of the individual, the number of the eruptions, and the existence of other particular conditions, such as scrofula, pregnancy, amenorrhœa, the change of life, &c. When chronic impetigo occurs on the head, on the upper lip, or any other region covered with hair, it often proves a very obstinate and troublesome disorder; especially if the patient be of advanced age, of a scrofulous diathesis, or a shattered constitution. But, under no circumstances, can it be regarded as attended by danger. The sudden suppression of the more severe forms of the eruption, particularly those affecting the face and scalp of children, may, however, be productive of most serious disease.

16. IV. Causes. — Impetigo is not communicated by infection. It is most frequently observed among the poor, ill-lodged, badly fed, and filthily disposed classes. Its exciting causes are, however, sometimes obscure. Individuals of a sanguineous or sanguineo-melancholic or lymphatic temperament, and scrofulous constitution, with a thin, soft skin, are most liable to it. In them it is occasionally excited by violent exercise, by intemperance of any kind, or by the depressing passions of the mind, as grief, disappointment, fear, &c. It is very often preceded by headach, languor, and disorder of the alimentary canal, and cannot be traced to any other exciting cause than this disorder. — Infants at the breast, and children during teething, particularly the lymphatic and scrofulous, are most liable to the varieties affecting the face and scalp. Young persons with fine skins are sometimes attacked with that of the face, on exposure to a hot sun. Females, on the apppearance, and on the cessation, of the catamenia, are also apt to be affected with this complaint. Several external causes may, however, excite pustules of impetigo, by acting directly on the skin. Persons who handle irritating substances, as raw sugar, lime, or metallic dust, often have impetiginous eruptions on the hands. Bateman regards the pustules, caused by the ointment of tartarised antimony, as a species of this disease; but they are of an entirely different character, and cannot be classed among any of its varieties. I believe, that disorder of the digestive organs, and accumulations of mucous sordes and other secretions in the *primæ viæ*, more commonly occasion impetigo than is generally supposed. I scarcely have seen a case, in which this derangement was not manifest either before, or in the course of, treatment; and in which this eruption was not evidently symptomatic of it. In this opinion I am supported by Mr. Dendy, my late colleague at the Infirmary for Children, where cases of this kind came frequently before us.

17. V. Treatment. — i. Whatever be the variety of simple impetigo, one mode of treatment is indicated. In the commencement of the disease, Willan and Bateman recommend the internal administration of *sulphur*, but not in sufficient quantity to produce purging; and if there is much inflammatory irritation of the cuticle, *soda*, *nitre*, or the *bitartrate* of *potash*, with which some of the *vegetable acids*, as *citric acid*, or *lime juice*, may be advantageously combined. The indiscriminate employment of sulphur has, however, sometimes aggravated the symptoms, and favoured the re-appearance of the eruption. I have prescribed, with marked benefit, the *sub-borate of soda* in emollient vehicles, either with or without small doses of nitre, or of the bitartrate of potash. — *Bloodlettings*, either general or local, have been proposed in extensive attacks of *impetigo figurata*, and in plethoric individuals may be of advantage; but, in general, they are not productive of benefit, and in persons of a weak and scrofulous habit of body are detrimental. If the eruption is attended by much fever, *calomel* and *antimonials*, or other mild mercurials, cooling *saline solutions*, and *diaphoretics* with *diuretics*, will be of service.

18. Locally, emollient fomentations, such as the decoction of mallows, digitalis, poppy heads, &c., and ablution with tepid water, are of the most essential service in the incipient stage of this disease, especially of the common saline mixture, with conium, be given at the same time. At a later period, saturnine or alkaline lotions, and the application of the ointment of the *acetate of lead* or *oxide of zinc*, will accelerate the cure, and will be often sufficient to effect it.

19. ii. When this affection occurs in children at the period of dentition, simple cleanliness is frequently all that is required. Here the eruption is occasionally accompanied by a manifest improvement in the constitution, and it would be highly imprudent, and even injurious, to check or repel it. If it occurs on the hairy scalp or face (§ 10.), the hair must be removed, and emollient applications resorted to. Where there is much local inflammation, or in plethoric children, *leeches* ought to be applied behind the ears. *Saline purgatives*, as the sulphate of soda, sulphate of magnesia, or tartrate of potash and soda, may be given with advantage in these cases, in doses of from two drachms to half an ounce daily.— If the disease, wherever occurring, proves obstinate, it has been usually treated by an alterative mercurial course, particularly *Plummer's pill*, or the *hydrargyrum cum cretâ*, with the decoction of *sarsaparilla* or *cinchona*; but a more beneficial effect has been derived from the exhibition of fine or six grains of *calomel* at bedtime, followed by a brisk *cathartic* the next morning, and a moderate dose of the *liquor arsenicalis*, taken three times a day, in the decoction of *elm bark*.

20. iii. As to *local means*, almost every variety has been tried in this disease. In some instances the patient cannot bear the most soothing and emollient applications; while, in others, the most stimulant have been employed with advantage. Where the irritation is insupportable, the use of the *hydrocyanic acid* has been suggested by Dr. A. T. Thomson, in the proportion of one fluid-drachm to four fluid-ounces of water, combined with one drachm of *alcohol*, and six or eight grains of *acetate of lead*; and subsequent expe-

rience has shown the value of this application. It sooths the irritation, and disposes the skin to regain its healthy action: but it must not be applied without caution; as cases have been recorded, where it became absorbed into the system, and produced depressing effects on the constitution, with considerable intermission of the pulse. These unpleasant symptoms, however, ceased on discontinuing it. It is useless to apply any local remedies, until the thick incrustations, which occur in *impetigo scabida*, are removed by emollient poultices, or by a weak decoction of poppies, or by exposing the surfaces to the vapour of hot water, &c. Any of the mild ointments before mentioned may afterwards be applied, and the surface should be covered with pledgets of soft lint, or the whole should be touched with a solution of *nitrate of silver*; or, if the skin is not very irritable, and the attendant inflammation but slight, while at the same time the disease has become chronic, the baths of Harrowgate, or artifical *fumigations of sulphur*, the hot air and *vapour baths*, and the *alkaline* and *sulphureo-gelatinous baths* will frequently both procure the removal, and prevent the recurrence, of the eruption. But in the more inflammatory cases, and in plethoric persons, bloodletting should precede a course of these baths. With the same intention, the baths of Barèges, Loüesche, Cauterets, Enghien, and many other Continental springs, have been recommended. Great benefit has also been derived from the warm sea-water bath, especially when followed by a course of sea bathing; it should, however, be remembered that salt water is injurious during any actual inflammation. But great discrimination is always required in the treatment of this eruption. Where there are much inflammation and irritability of surface, the internal remedies should be of a cooling and sedative nature; and the external applications, emollient and palliative; — in an opposite state, the *arsenical solution* may be given; and slightly stimulant ointments, such as the ointment of nitrate of mercury diluted with six or seven parts of simple ointment, or an ointment of trisnitrate of bismuth, may be applied. — In all cases, the *diet* of the patient should be restricted, and animal food taken in very moderate quantity: milk and farinaceous food are the most appropriate. Fermented liquors, spirits, and wine, ought to be strictly forbidden.

21. iv. In *impetigo erysipelatodes*, antiphlogistic means must be early adopted. *Purgative medicines*, especially the infusion of senna with full doses of the alkaline carbonates, and the *neutral salts* with *antimonials* and *nitre*, will materially alleviate the fever; but when the discharge is copious, and incrustations begin to be formed, the greatest benefit will be derived from the *decoction of cinchona* with *hydrochloric*, or dilute *sulphuric acid*.— If the disease becomes chronic, a slight alterative course of *mercury* and of *sarsaparilla* generally proves beneficial. The *solution of potash* and the *alkaline carbonates* are also serviceable, when taken in tonic infusions. The *local remedies*, which were recommended in the other forms of the disease, namely, emollient fomentations and tepid ablutions, mild ointments applied to the excoriated surfaces, and sea bathing, or sulphureous fumigation on the decline of the eruption, will also be required in this variety.

IMPOTENCE AND STERILITY. — Syn. *Impotentia Generandi*, *Sterilitas*; 'Αναφροδισια, *Anaphrodisia* (from α, neg., and ἀφροδισια, and that from 'Αφροδιτη, Venus), Auct. var. *Impuissance*, Fr. *Unvermögen zum Beyschlaf*, *Ohnmächtigheit*, Germ. *Impotenza*, Ital.

Classif. — 4. *Class*; 1. *Order* (*Cullen*). 5. *Class*; 2. *Order* (*Good*). I. Class, II. Order (*Author*).

1. Defin. — *Incapacity of sexual intercourse, and inability of procreation.*

2. *Impotence* and *Sterility* are so intimately related, that they must necessarily be considered under one head, although disjoined by Good and some other nosologists. They are subjects of much greater practical importance than has been conceived by many, and often involve the happiness and perpetuation of families. Yet have they, by a sort of professional prudery, been either entirely overlooked by medical writers, or very imperfectly discussed, and thereby relinquished to the irregular practitioner, or to the entirely unqualified empiric. In the present æra of high refinement, and of luxurious, if not vicious, enjoyments; and under the influence of noxious plans and systems of education; instances are very numerous, for which medical advice is required for the removal of the morbidly disqualifying conditions about to be considered, but is not resorted to so frequently as it ought to be. Since advice is thus often necessary, the ability of those, from whom the community have a right to expect it of the most judicious kind, should be equally great in providing it. There is every reason, also, to believe, that it would be oftener sought after, if the subject were known to be more fully entertained by the duly qualified members of the profession. The practical consideration only of these morbid conditions falls within my plan: their legal relations are very ably discussed in the classical works of Paris, Beck, and Smith.

3. *Impotence* may exist in either sex, but most commonly in the male, owing to the sexual conformation. *Sterility* most frequently depends upon the female, although it sometimes is owing to the male; and, in a practical point of view, if not in a medico-legal one, it is more frequently thus owing, than is stated in books.

4. *Impotence* and *Sterility*, in respect of both sexes, have been differently arranged by writers; — into *absolute* and *relative*; *constitutional* and *local*; *direct* and *indirect*; *permanent* and *temporary*; and, by Dr. Beck, into *absolute*, *curable*, and *accidental*. These distinctions are all of importance in the consideration of the subject; but the divisions founded on the nature of the causes are more useful. — M. Raige Delorme has ar-

ranged impotence into — 1. that depending upon lesions of the sexual organs; — 2. that proceeding from disorder or interruption of seminal emission; — and, 3. that caused by defect of the faculty of erection. The division adopted by Dr. Beatty, into — 1. Organic; — 2. Functional; — and, 3. Moral; — although not materially different from the foregoing, is preferable to it. — I shall consider the subject with reference — *first*, to the male, and, *secondly*, to the female; and view in succession the *mental*, the *functional*, and the *organic* states, from which impotence and sterility most frequently proceed.

5. I. Impotence in the Male — *Agonia, Agenesia, Impotentia Generandi Masculina, Sterilitas Paterna, Dyspermatismus, Dyspermasia,* Auct. var. — *Male Sterility* — may depend upon — 1. Mental influences or causes; — 2. Functional disorder; — and, 3. Organic lesions of the sexual organs. — 1st. *Mental influences or causes* may occasion *temporary*, or more or less *prolonged, impotence,* even in persons of a sound constitution in every respect. In them, the removal of the cause leaves the generative organs in a condition capable of performing their functions. The moral or mental influences, which most frequently occasion impotence, are, chiefly, too eager, too violent, or overexcited desire, affections of the imagination, and the depressing passions. Fear of incapacity, or of not being loved, timidity, shame, disgust, hatred, jealousy, surprise, terror, or any of the more violent mental emotions, most commonly have this effect. The first of these causes is, however, the most frequent; and the second, — the influence of the imagination, — the most powerful and permanent. In former times, when superstition, and a belief in the power of magicians, of incantations, of sorcery and witchcraft, prevailed, the state of the imagination was often not only the cause, but also the cure, of this affection; and, whilst incantations and other modes of impressing the mind were resorted to, for the purpose of destroying sexual power, amulets and charms were worn, not only for the purpose of guarding against their effects, but also for the restoration of this power, when lost or impaired. In the East and in Egypt, in Greece and in Rome, in uncivilised countries and in the seats of civilisation, until a belief in witchcraft ceased, these means were daily resorted to, as well as others, which could operate only through the medium of the imagination. The bane and the antidote were both confided in, however obscure, or impenetrable, or even absurd, either of them might have been. Montaigne was the first to penetrate and to expose the mystery of their operation. The twentieth chapter of the first book of his *Essays* will be read both with interest and instruction; and the thirty-seventh chapter of the second book will he found not less profitable to the practitioner of the present day.

6. 2d. *The generative function may be variously impaired,* and by diversified causes. — M. Virey remarks, with his accustomed desire of effect rather than of accuracy, that "the genital organs offer two states during life in the young and old, which are the frozen zones of existence, the intermediate period being the torrid zone of life. The child has nothing to give, the old has lost all." Instances, however, occasionally occur of genital precocity; and those in which the function continues till a late period of life, are by no means infrequent. The generative function appears with puberty, and continues until the sixty-fifth year, or even much later, unless impaired by excesses, or by local or constitutional disease. During, however, this long period, numerous circumstances tend to weaken or permanently to destroy it. The constitution and energy of the parents are sometimes the cause of the imbecility of the offspring. Children from premature connection, or of exhausted, aged, or worn-out persons, often inherit the incapacity of their parents, in respect both of the function in question, and of the system generally. Those, who are thus *hereditarily* or *constitutionally* impotent, are of a leucophlegmatic or lymphatic temperament; their soft solids, especially the fibrous and muscular structures, are soft, lax, and weak; their forms are rounded, from the superabundance of cellular and adipose substance; their hair is soft and fine, and deficient on the face and pubes; their frames are delicate and feminine; their voices are shrill, clear, sharp, or weak; and their testes are small and soft, the cords and scrotum being soft, lax, and pendulous.

7. Functional impotence is most commonly caused by premature or excessive venereal indulgences, and especially by the pernicious crime of manustrupatio. By these most injurious habits, the organs are excited to action before they are fully developed, and the seminal fluid excreted before it is duly elaborated. The muscles concerned in the generative function, and those also of the lower extremities, are either imperfectly formed, or have their energy remarkably impaired, so that they become susceptible, vacillating, and ultimately nearly paralysed. The imagination is morbidly acute or excitable, and erection imperfect, or frequent and momentary. The seminal and prostatic secretions are consequently weak, thin, clear, scanty, and serous; the whole frame, and particularly the nervous system, languish, and become enfeebled by the too frequent discharge of a fluid essentially vital, partly recrementitious, and necessary to their support; and ultimately the testes emaciate, or become soft. The variety of impotence noticed by Dr. Paris, depending upon a want of consent between the male organs of generation; or that in which erection takes place without discharge, or in which this latter occurs too quickly, and after imperfect erection; is most commonly the consequence of the causes just mentioned. But, in such, the evacuation consists chiefly of the prostatic fluid. General debility, from imperfect or unwholesome nourishment, may weaken the procreative energy, or render the desire less frequent, but it rarely destroys it altogether, or even for a time. Severe diseases, intense application to study, or to abstract inquiries or pursuits, have a still more remarkable effect in impairing, or temporarily destroying, the generative functions. In some instances, prolonged disuse of this function is followed by wasting of the testes, and, consequently, permanent impotence is the result. These organs, like others of the œconomy, are strengthened by moderate use, are weakened by abuse; their functions being often entirely lost by protracted disuse.

8. There are various other causes which may occasion functional impotence, particularly in certain constitutions; as the use of narcotics, espe-

cially of tobacco, hyoscyamus (Marc), cicuta, and opium. The sedative gases (Fodéré), particularly carbonic acid gas, may produce it. Various refrigerants have a similar influence, as nitre, the carbonates of soda, camphor (Diemerbroeck and Lossius), and some cooling diuretics. The smell of camphor has long been considered as anaphrodisiac; and colchicum has certainly this effect, as noticed by Dr. Beatty. Soda water also exerts the same influence. The effect of these, however, are only temporary or partial. — Injuries of the spine or spinal cord, or of the head, particularly the occiput (Marcellus Donatus, Fabricius Hildanus, Hennen); venæsection behind the ears (Hippocrates); arteriotomy, &c.; have been considered causes of impotency. Of the influence of the first of these there can be no doubt. The use of mercury has been assigned as a cause; but it can hardly be viewed as such, unless carried to excess.

9. 3d. *Organic lesions* occasioning impotency, are — (*a*) Diseases of the generative organs or of adjoining parts; — (*b*) Malformations of these organs; — and (*c*) Deficiency of one or more of them. — Anaphrodisia from the *first* of these is often only temporary or relative; but from the *second* and *third*, it is generally absolute and permanent. *A*. The *diseases* which most frequently cause impotency are — *firstly*, those of the penis; *secondly*, of the testes; and, *thirdly*, of adjoining parts. *a*. The *penis* may be so excessively irritated as to occasion a temporary impotence by obstructing the opening of the seminal ducts and the urethra. Much more frequently, however, complete or partial paralysis, or deficient energy of the nerves, and consequently of the muscular and vascular action of the organ, occurs, constituting the *anaphrodisia paralytica* of authors. This latter state is merely an aggravated form of functional impotence, and most commonly produced as above stated. A singular instance in which the cells of the corpora cavernosa were apparently disorganised or altered by inflammation and suppuration, so as to prevent the influx of blood, and consequent distention of the penis, and to occasion impotence, has been recorded by Mr. Callaway. A similar change to this may take place in one side of the organ, and have nearly the same effect upon its functions.

10. Various obstructions to the seminal discharge occasion temporary or permanent impotency. The chief of these are strictures of the urethra, and disease of the seminal ducts. Fodéré (*Med. Leg.* lib. i. p. 382.) adduces two cases, in which the powers of copulation existed, but without the seminal discharge. In one, the ducts were obstructed by hard concretions; in the other, they were constricted and callous. As stated by Dr. Beatty, the opening of the conjoined ducts of the vasicules seminales and vasa deferentia may be closed by scirrhous enlargement of the neck of the bladder, by enlargement of the prostate gland, by scirrhosity of the verumontanum, or by lesions of the duct itself. Strictures of the urethra can hardly be considered a cause of impotency, unless they are so extreme as not to permit the passage of a fine bougie. In the states of disease just mentioned, the inability of procreation arises from obstruction to the discharge of the seminal fluid, which is duly secreted; and when the obstruction is seated in the urethra, it may be removed by modern surgery. M. Fodéré and Dr. Dunlop state that double scrotal hernia, by pressing upon the spermatic cords, sometimes causes as complete emasculation, as if the testes were entirely removed.

11. *b*. Impotency may also depend upon organic *lesions of the testes* — upon scirrhus, carcinoma, fungoid disease, or scrophula of these organs. But unless the whole structure of both organs be changed, the faculty of procreation may not be entirely or permanently lost. Uncommon smallness of these organs may occasion only temporary impotency; for this state may depend upon delayed evolution, or arise from the wasting consequent upon disuse. Mr. Wilson mentions the case of a person, twenty-six years of age, in whom the penis and testes remained of the same size as in childhood. He married at this age, and at twenty-eight, the organs had reached their natural size. When, with smallness, there are remarkable flaccidity and softness conjoined, impotency is much more complete and even permanent. In a case of this kind in a strong young man, sometime under my care, no benefit resulted from treatment. Severe *bruises* of the testes may be followed by wasting or disorganisation of them. Dr. J. G. Smith alludes to this mode of making eunuchs, and states that it sometimes failed. I believe that most of the instances in which impotency has been said to have been produced by riding, have been owing to bruises or injury of these organs, or to the pressure to which they have often been subjected. Wasting of the testes may, however, arise without any very obvious cause. In the extreme case in which I was consulted, I was unable to ascertain its source. It occurred in a most robust and muscular young man, who would not admit that he had ever had recourse to excessive or vicious indulgence, or that he had been unusually continent, until his inclination ceased with the decay of the organs. Fodéré states that it was a common disease among the labourers in the canal at Arles; and Larrey, that it was not uncommon among the French troops on their return from Egypt. It has sometimes occurred as a consequence of the metastasis of *Cynanche parotidæa* to the testes. — *Induration* of these organs, independently of scirrhous disorganisation, may be so great as to destroy their functions. According to M. Andral, the seminiferous tubes are entirely obliterated, and the structure of the organ is hard, homogeneous, and without trace of organisation in cases of extreme induration. Impotence from inflammation of the testes is only temporary.

12. *c*. The *lesions of adjoining parts* occasioning impotency, are chiefly, uncommon obesity, very large scrotal hernia, and hydrocele. Neither of them requires any mark. A varicose state of the spermatic veins may also have this effect, when it is very remarkable. But I am unacquainted with cases in which this cause has been assigned.

13. *B*. *Malformations of the male genitals* may occasion impotency. Great size of the penis is seldom, and smallness of the organ is, perhaps, never a cause of it, if the functions of the testes are duly performed. According to Zacchias, Fodéré, Beatty, and others, excessive size, particularly excess in length, may produce relative or temporary impotence, by injuring the female organs. The chief malformations of the penis having this effect absolutely or permanently, are those in which the urethra terminates in the pe-

rineum; and even in these, impregnation may be accomplished by art. John Hunter was consulted in a case of this description, and was induced, by the experiments of Spallanzani, to recommend the patient to collect the seminal fluid emitted from the perineum during intercourse, and to inject it into the vagina. Impregnation took place, and a healthy child was born in nine months.

13. In cases where the urethra opens in a part of the penis admitting of being introduced within the vagina, impotency may exist, but it is only relative; for procreation may be effected when the opening is thus situated, whether it be on the dorsum (*epispadias*), or on the inferior surface (*hypospadias*), as more frequently observed. Numerous instances are recorded by Simeons, Belloc, Kopp, Blundell, and Foderé, of impregnation by persons in whom these malformations existed. Mr. J. Hunter met with a case, in which the epididymis terminated in a cul-de-sac, instead of passing to a vas deferens. Dr. Beatty states, that a similar conformation sometimes exists in the vesiculæ seminales, where, instead of entering the urethra, they terminate, after being joined by the vasa deferentia in shut sacs. When these formations of the excretory ducts of the testes exist on both sides, absolute impotency necessarily results, but they are extremely rare.

14. *C. Deficiency of one or more of the male organs* occasions absolute or relative impotency. *a.* Congenital deficiency of the *penis* is rarely observed, and complete deficiency, still more rarely. Mr. Foderé mentions a case in which no vestige of the organ existed from birth. The testes were perfect, and sexual desire was not impaired. In most of the instances of congenital partial deficiency or malformation of the *penis*, recorded by authors, the urinary organs presented other malformations, particularly in respect of the urinary bladder and ureters. This is illustrated by several cases in Dr. Duncan's Memoir on this subject. (*Edin. Med.* and *Surg. Jour.* vol. xxv. p. 31.). *Accidental* deficiency of the penis is sometimes met with. The organ may have been either amputated or destroyed by disease. Some years ago, a surgeon, a friend of the author, was sent for in great haste. He found a man in a state of syncope from hæmorrhage proceeding from a very recent amputation of the penis close to the pubis. The strictest secrecy was preserved as to the cause and mode of amputation, which had evidently been effected by a sharp instrument.

15. The glans penis, and indeed the greater part of the organ, may be lost without causing more than relative impotency; and possibly, nearly all of it may be removed without producing an absolute loss of the procreative faculty, if the means resorted to by John Hunter (§ 12.) be employed. Instances of extensive mutilation of this organ, without destroying this power, are referred to by Frank, Paris, Beatty, and others; and although there is every reason to conclude that a complete removal of the penis will generally occasion impotency, yet the proper function of this part being to excite the female organs, and to convey the prolific fluid to the parts destined to receive it, if these purposes can be at all accomplished, impregnation may follow.

16. *b.* Congenital deficiency of the *testes* is rarely observed; and most of the cases in which these organs have been said to have been wanting, are merely instances of their retention in the abdomen. When they are not found in the scrotum, their entire absence can be inferred only from the history of the case, and from the state and appearances of the patient; for when they are altogether wanting, the usual characters of the male are partially lost, and those of the female assumed. As delay in the descent of the testes may arise from some imperfection, or delay of development, as J. Hunter reasonably infers, certain of the female characters may be presented, and yet these organs may exist nevertheless. The question then is, whether or not, the state of development, to which they may have attained, is sufficient for procreation. M. Marc adduces the case of a person of a feminine appearance, who yet possessed the full procreative power. The external characters cannot therefore always be confided in; but when all the external appearances of virility are present, although the testes are not found in the scrotum, there is every reason to infer that impotency does not exist; for numerous instances are on record proving that the mere retention of these organs within the abdominal ring does not affect the procreative power.

17. The congenital absence, destruction, or removal, of one testis is not a cause of impotency. It may however be a cause of relative incompetency and even of complete impotence, if the remaining one be soft, small, or withered. Castration, or the removal of both testes is followed by complete and permanent impotence, if it have been performed before puberty. But, subsequently to this period, the power of procreation may exist for a very short time after its performance, owing to the seminal fluid collected in the vesiculæ seminales previously to the operation. M. Marc supposes that the time taken for the cure of the wound is sufficient for the absorption of this fluid into the circulation; but the cases adduced by M. Boyer and Sir A. Cooper prove that a temporary power exists or is retained until the vesiculæ seminales are emptied. On this subject, the works of Paris and Beck will be consulted with advantage, for it hardly comes within the scope of this work.

18. II. Impotence and Sterility in the Female. A female may be impotent but not sterile, and she may be sterile, but not impotent; for, as respects the former condition, a state of the sexual organs may exist sufficient to prevent intercourse, and yet, upon its removal, impregnation may take place; and, as regards the latter condition, perfect competency to intercourse may exist, and yet conception may never occur. She may also be both impotent and sterile, or, in other words, were the impediment to due intercourse entirely removed, impregnation might not be effected. Sterility is very much more common than impotency in the female, and even than impotency in the male.

19. *A. The causes of* Impotence *in the female* are an impervious state of the vagina, absence of this canal, remarkable constrictions of it, the division of it by a septum running downwards from a double uterus, adhesions of the sides of the vagina, or of the labia, and the termination of the passage abruptly in a cul-de-sac. An impervious vagina may arise from changes in the soft parts, consequent upon protracted inflammation or irritation, the passage becoming first constricted or remarkably contracted, and ultimately obliterated. In a case respecting which I was consulted, a recto-vaginal fistula, seated at the upper part of the va-

gina, had occasioned so remarkable a contraction of the vagina, that its canal was almost obliterated, its parietes having become callous and indurated, A similar result may also follow a vesico-vaginal fistula. **Fodéré** believes, that malformations of the bones of the pelvis may be so great as to prevent intercourse, but this can hardly be the case. Exostoses, however, on the internal or inferior surface of the bones of the pubis may have this effect, but their occurrence in this situation, and to this extent, must be very rare. Congenital absence of the vagina has been met with by **Villaume**, **Moulon**, **Syme**, and **Warren**; and absence of both vagina and uterus by **Mott**, **Davis**, **Macfarlane**, and others. In a case adduced by **Foderé**, the uterus and vagina were found, upon dissection, to constitute one solid mass, without any cavity in either. In a child, examined after death by **Hufeland**, no trace of genital organs, peculiar to either sex, was found, externally or internally. Although such instances are rare, there is no doubt that one or more of the different parts forming the female organs may be wanting. Congenital narrowness of this passage has been observed in a very few instances. In one or two of these, however, impregnation occurred, and the passage became enlarged in the progress of gestation. Contraction of the vagina was said to have existed in the celebrated Joan of Arc. The division of the canal by a septum has been met with in a very few cases only. Firm adhesions of the labia pudendi are not unfrequent in children, in consequence of neglected excoriation or inflammation. I have seen several instances of these adhesions of various extent, duration, and firmness. They are more rare in females after the age of puberty; but they have been met with at this age by **Benevoli**, **Merriman**, **Ryan**, **Tucker**, and others, and in some cases, they have been so complete, as nearly to prevent micturition. Inflammation or injuries, by instrument, or otherwise, during parturition, have been followed by adhesion of the sides of the vagina, and total obliteration of the canal. Several of the instances of obstruction by a strong membrane placed at the commencement, or in some part of the passage, recorded by **Fabricius Hildanus**, **Ruysch**, **Ambrose Paré**, **Benevoli**, **Foderé**, **Physick**, and others, may be imputed to adhesions long previously formed, which have subsequently assumed an organised and membranous state, rather than to an inordinately firm and resistant hymen. The hymen may, however, be thickened and hypertrophied, and be a cause of impotence by preventing intercourse. Yet impregnation may be effected nevertheless, as proved by numerous cases. This state of the membrane is therefore not productive of absolute impotence, even should it be allowed to continue; and it is not a permanent cause, as it may always be removed by an operation. Complete prolapsus or procidentia of the uterus, retroversion of the uterus, prolapsus of the vagina, cancer of the vagina or uterus, and extreme brevity of the vagina, are generally productive of impotency, although impregnation has occurred in rare instances, notwithstanding these lesions.

20. *B.* **Sterility** may proceed from absence of the uterus, or of the ovaria, or of both. When the uterus is wanting, the vagina is usually short. It may also proceed from a scirrhous or indurated state of this organ, from tumours in its substance, from polypi in its cavity, or attached to its neck, from occlusion of the Fallopian tubes, or adhesion of their fimbriated extremities to adjoining parts, from narrowness or entire obstruction of the os uteri, and from disease of both ovaria. Several of these require further remark. Extreme constriction of the os uteri has been shown by Dr. **Macintosh** to be productive of difficult, painful, or obstructed menstruation, and it most probably is also one of the causes of sterility. The mouth of the uterus may be completely obstructed by agglutination of its sides, or by a false membrane stretched across it, either internally or externally. The openings of the Fallopian tubes may be also closed by a membranous production, or by an albuminous exudation from the internal surface of the uterus. The tubes may be either partially or altogether obliterated, in consequence of the extension of inflammatory action to them, from the uterus or adjoining parts. When these alterations extend to both tubes, sterility must necessarily result. Although tumours developed in the body or neck of the uterus, and polypi attached to its internal surface, generally prevent impregnation, yet instances have occurred, in which conception has nevertheless taken place. These are however, very rare, and abortion has always occurred during the early months. A tumour or polypus may be formed on the internal surface of the uterus, and yet after its removal, the patient may conceive and bear a child at the full time. A case illustrative of this has been recorded by Dr. **Beatty**.

21. The above causes are mostly productive of absolute or permanent sterility; but there are others, which are either relative, or admit of removal. These are chiefly, too profuse, or too frequent, and difficult menstruation, constant or profuse leucorrhea, inflammatory affections of the uterus, or of its appendages, dislike, disgust, and indifference on the part of the female, &c. Profuse or frequent menstruation is a more common cause of sterility than is generally supposed; this state, particularly when associated with irritation of, or increased vascular determination to, the womb, preventing the retention of the ovum, until it has undergone the changes necessary to its attachment to the uterus. Leucorrhea is a cause of sterility chiefly when it depends upon inflammatory irritation of the internal surface or neck of the uterus, or when the secretion proceeds from relaxation of the vessels in this situation. When it is a consequence of inflammatory action, sterility may continue after the discharge has ceased, owing to organic changes in the surface of the uterus, or in the Fallopian tubes, especially the formation of a false membrane in the former, and the production of an albuminous exudation in the canals of the latter, or consequent obliteration of them. When barrenness depends upon leucorrhea proceeding from local relaxation, or general debility, it may be removed upon the disappearance of its cause. Delayed, retained, obstructed, or suppressed menstruation frequently occasions sterility. Some females have, however, conceived, who have never menstruated; and the mere suppression or obstruction of the catamenia may or may not prevent impregnation; various other contingent changes, or concurring circumstances, either favouring or preventing this result. Difficult menstruation is sometimes a cause of sterility, but its influence also will depend much upon other circumstances. That form, however, of dysmenorrhea, described

by Dr. DUNCAN and Dr. DEWEES, which appears to depend upon the formation of a membranous substance in the uterus, having a strong resemblance to the decidua, is very generally productive of barrenness; but this is only one of the several forms which subacute or chronic inflammation of the uterus assumes, either of which may occasion temporary or permanent sterility.

22. There are other causes of temporary or relative sterility. Among these the most common are too frequent, yet inefficient sexual intercourse, too early marriages, general ill-health, and debility or exhaustion of the female organs, owing to premature or too frequent excitement. Various circumstances connected with sterility in prostitutes have, perhaps, thrown some light upon certain of the causes of this state; and particularly the fact, that many of this class have had children after marriage, or after relinquishing promiscuous intercourse. Numerous instances have occurred of females who, having been obliged to marry contrary to their inclinations, have not conceived, and yet have had children from a second marriage. It is generally understood by females of all ranks in society, that indifference during intercourse, or suppression of the orgasm will prevent impregnation; and, although they are sometimes deceived in this respect, yet their inference is correct in the majority. This is one of the principal causes of the sterility of prostitutes, other circumstances, however, besides those just alluded to, combining with it, to produce this effect in them.

23. III. TREATMENT. The treatment of impotence and sterility depends entirely upon the causes of either the one or the other, as far as they can be known. Many of these causes may be fully ascertained, and the consequences correctly anticipated; but as to the existence of others, inferences only can be drawn from a number of circumstances, and these inferences cannot be always fully confided in. Most of the organic lesions and deficiencies, enumerated above, cannot be remedied, yet a few of them may be assisted by art, either temporarily or permanently. But many of the functional and moral causes, and their effects, may be entirely removed. Absence of an organ or part essential to the function of generation in either sex is generally productive of impotence and sterility. Yet an imperfection only, and disease, of one or more of these organs occasioning either inability in the male or barrenness in the female, may be remedied. Adhesions of the prepuce to the glans penis, phymosis, strictures of the urethra, fistulous openings in the course of the urethra, some of the diseases of adjoining parts that prevent intercourse, paralytic and debilitated states of the penis, and the slighter injuries of the testes, may be permanently removed, and their consequences disappear. Contractions of the vagina, and even constriction or narrowness of the os uteri, occlusion of the entrance of the vagina by adhesions of the labia, or by a morbidly dense hymen, or by a false membrane, prolapsus or procidentia of the uterus or vagina, uterine polypi, leucorrhea, difficult or painful menstruation, and inflammatory states of the uterus may be severally remedied, and, although sterility may not be always, it will be frequently, also removed.

24. Cases of impotence and sterility from moral and functional causes are the most common; and, although they require the most scientific and judicious treatment, yet the mental, as well as the physical imbecility, that often characterises them, brings them more frequently in the hands of pretenders and empirics, than in those of the qualified practitioner. The cases which proceed from these causes may be arranged into 1st. Those which depend upon exhaustion; 2d. Those which proceed from disuse, or from an imperfect exertion, of the function; and, 3d. Those which arise from excessive mental and physical excitement, relatively to the susceptibility and sensibility of the nervous system.—*a.* When impotency and sterility proceed from *exhaustion*, or from a premature decay of the generative functions, owing to premature, unnatural, or excessive excitement, the treatment is nearly the same in both sexes, according as either may be chiefly or solely affected. In these cases the indications are, to restore — 1st. The energies of the constitution; and 2d. The functions of the procreative organs. To attempt the second, without either previously or contemporaneously fulfilling the first indication, will generally be futile, and often injurious. Persons, who are thus exhausted, sometimes perpetuate their infirmity by having recourse to noxious excitants, and to the means advised by empirics. The scientific practitioner will be guided in the selection of remedies, by the causes, circumstances, and phenomena, connected with the case; and he will find it necessary to associate a moral or mental regimen with the physical means which may be required. When the affection depends upon an excited imagination, in connection with a depraved habit, the former part of the treatment is the most necessary, but the most unpleasant for the physician to prescribe, and the most difficult for the patient to adopt. In these cases the mental weakness has advanced, *pari passu*, with the constitutional and local infirmity, until the mind has become incapable of exerting its more reflecting and moral powers. It will, therefore, be often necessary to restore the energy of the nervous system by suitable diet, appropriate medicines, regimen, occupation, and change of air, before the moral part of the treatment will receive due attention from the patient.

25. In other and slighter cases, the debility is principally local, the general health as well as the mental energies, remaining only partially or but little impaired. In these, the local, constitutional, and moral means of cure, will frequently prove successful, especially in the male. In this sex, when the inability depends chiefly upon weakness of the sexual muscles, invigorating modes of treatment, general and local, usually remove it, if its causes be avoided. In all these, attention to the digestive and secreting functions, vegetable or mineral tonics, especially the preparations of iron, and chalybeate mineral waters, the shower bath, or the cold salt-water bath with regular exercise in the open air, mental occupation, and early hours, will generally be most beneficial. Where the patient is subject to discharges from the urethra upon passing a stool, or on the excitement of sexual desire, a turgid and irritable state of the prostate gland may be inferred. When he is liable to frequent emissions during sleep, an irritable condition of the testes, and of the *vesiculæ seminales* obviously exists. In these, the more cooling tonics and the more astringent chalybeates may be employed, particularly the mine-

ral acids, alone or with bitter infusions, and the tincture of the muriate of iron, aided by the regimen already stated. When the general and local astheniæ are great, a moderate use of wine, of warm spices and aromatics, with as full and nutricious diet as the digestive organs can dispose of, will also be requisite. But the mental and local causes of sexual excitement should be avoided, so that the function should not be exerted beyond what may be necessary to restore and to fortify it.

26. When impotence in the male depends upon a too frequent exertion of the sexual function, the means of cure are sufficiently obvious. Yet the patient may be unable, from mental or nervous weakness, to exert the control necessary for its cure. In such a case the usual restorative remedies should be prescribed, especially chalybeates and cold sea-water bathing. In most of these, the male organs are so irritable, that their functions are performed too rapidly and imperfectly, or before the organs, more or less necessary to procreation, can be excited in the female. At the same time, the male secretions are inadequate, particularly in respect of elaboration and retention in the *vesiculæ seminales*, for the accomplishment of the purpose for which they are intended. This form of male impotence and sterility is commonly produced by masturbation, and is most benefited by whatever will improve the general health, and restore the tone of the sexual organs. Attempts at intercourse in these cases should not be more frequently than may strengthen or promote the function, without exhausting or weakening it.

27. The *other states* (§ 7, 8.) of functional impotence and sterility above alluded to, hardly require a particular notice, as they are temporary only, and soon disappear, as circumstances generally arise which soon remove their causes. It is, indeed, chiefly to the removal of the causes, that the attention of the physician should be directed, in the treatment of this complaint in both sexes.

28. In ancient times, and recently in some countries, both civilised and savage, the removal of impotency and sterility by the use of heating substances, supposed to possess aphrodisiac properties, was generally attempted. The prematurely aged, worn out debauchees, and the community generally, in some parts, especially in China, Japan, Africa, &c., often employ substances which are reputed to possess these properties. But the effects they produce, when they produce any, are more commonly injurious than beneficial. Musk, ambergris, cantharides, phosphorus, opium, the hot spices, aromatics, coffee, vanilla, borax, genseng, castor, saffron, &c., are supposed to possess aphrodisiac virtues; and a diet consisting principally of fish or of shell-fish, has a similar repute. Circumstances may arise in which it may be proper to prescribe certain of these, as possessing stimulating and restorative properties; but others of them ought to be employed with extreme caution, particularly cantharides, phosphorus, and borax. The nostrums said to possess the virtues in question ought not to be resorted to. Certain articles of food, as pigeons, eggs, particularly raw or undressed eggs, caviàre, herrings recently pickled, oysters, truffles, &c., may be employed, as being at least harmless; but the less that heating medicines are prescribed the better, unless under certain circumstances, which may occur to require them; as in cases where the sexual function has not been restored after exhausting and depressing diseases, or after prolonged exertion of the mind on abstract subjects. I was very recently consulted by a gentleman about forty, who had no return of the sexual function after a severe attack of influenza a twelvemonth before. He had perfectly recovered from it in other respects for several months, and the remaining imperfection was a source of distress to him. In a case of this kind, the physician should at least know the means most likely to be of service, particularly as the inability may become a matter of family trouble, as well as of individual misery. KÆMPFER states, that a combination of musk, ambergris, opium, and aromatics, in the form of small pills, are much employed by the Chinese and Japanese as an aphrodisiac; and I believe that it is not without some degree of efficacy. But it is very obvious, that the prolonged or too frequent recourse to these and similar substances is most injurious, both morally and physically.

29. The *sterility of females* must be treated with strict reference to the causes, as far as they may be ascertained or inferred. When it is chiefly functional, and induced by exhaustion, or by the noxious practices already alluded to, the means of cure are very nearly the same as have been here recommended, especially attention to the digestive and uterine functions, the use of chalybeates, or of chalybeate or other tonic mineral springs, with air, exercise, and early hours. For them also, the cold salt-water bath, the shower bath, or the salt-water *douche* on the loins, will also be of great service. The importance of a due regulation of the mind, of healthy occupations, and of abstemiousness, should be duly estimated.

INDIGESTION.—Syn. Δυσπεψια (from δυς *with difficulty*, and πεπτω, *I digest*), βραδυπεψια, απεψια, Gr. *Concoctio tarda*, *Stomachi resolutio*, *Cruditas*, *Indigestio*, *Passio Stomachia*, Auct. Lat. *Apepsia*, Vogel. *Soda*, Linnæus. *Anorexia*, Sagar. *Bradypepsia*, Sauvages. *Dyspepsia*, Swediaur, Cullen, Parr. *Dyspepsia Simplex*, Young. *Limosis Dyspepsia*, Good. *Schwere Verdauung*, *Uebel Verdauung*, Germ. *Indigestion*, Fr. *Indigestione*, Ital. *Bad digestion*, *Slow digestion*, &c.

Classif. — 2. *Class*, Nervous Diseases; 2. *Order*, Defect of Vital Energy (*Cullen*). 1. *Class*, Diseases of the Digestive Function; 1. *Order*, Affecting the Alimentary Canal (*Good*). I. Class, I. Order (*Author*, in *Preface*).

1. Defin. — *Impaired or fastidious appetite; slow and difficult digestion; sensations of discomfort referrible to the stomach, and frequently costiveness.*

2. *Dyspepsia* or *indigestion* has been employed as the generic designation of several disorders ranged under it as species, by most modern writers, and particularly by Sauvages and Cullen. Young and Good have limited the meaning of the term, by considering some of those disorders as altogether distinct from it. Dr. Todd, however, in an able and comprehensive article on the subject, has applied this term to all the functional disorders of the alimentary canal. Having discussed several of the affections viewed by some writers as species of indigestion, in separate articles, according to their natures and seats (see articles, Cœcum, Colon, Costiveness, Duodenum, Flatulency, Pyrosis, Stomach, *Painful affections, and inflammation of*), my observations, at this place, will necessarily be confined to the simpler forms of this disorder.

3. *Indigestion* is either *primary* or *secondary*,—*idiopathic* or *symptomatic*, *simple* or *complicated*. When it is *complicated*, it may have been either the primary or the secondary affection. Dr. Todd distinguishes between symptomatic and sympathetic dyspepsia; and remarks that, "a *secondary* dyspepsia may be conveniently divided into *symptomatic*, forming only a part of a more general disease, and *sympathetic*, the consequence of consent with the disorder of some other organ." The distinction is, in some respects, wanting in precision, but it may be preserved as being one usually recognised.

4. The *varieties* or *forms* of indigestion have been variously described, named, and arranged, by the numerous recent writers on this disorder; and a most eager disposition has been evinced by all, to assign new terms, and to devise distinct pathological states, for each. In some instances, distinctions have been multiplied to an extent bewildering the inexperienced, and beyond the actual morbid manifestations of the organs affected. It will be readily admitted, that different forms of indigestion will depend upon different states of the stomach, and of its associated viscera; that, in one, the organic sensibility will be especially affected; in another, the secretions; in a third, the muscular contractility; in a fourth, the circulation; in a fifth, two or all of these functions; and that these particular affections will be variously associated with disorders of the liver, or of the pancreas, or of the duodenum, and not merely with these, but with others in remote organs. Yet these individual affections, even in their simpler or less complicated states, will seldom be manifested by symptoms enabling the most close observer to determine, with precision, which of them is the one actually present, either in a simple or predominant form, or the exact associations to which it may have given rise. It will, therefore, be proper not to multiply distinctions beyond those which will be found useful for practical purposes. The disorder which proceeds from a simple diminution of the functions of the stomach,—from impaired secretion, weakened organic contractility, and languid circulation—from asthenia of the organ,—will, with propriety, form one variety of indigestion; and that which depends upon a state of erethysm, or vascular irritation, approaching, but not amounting to, inflammation of the villous surface, will constitute another. This latter, especially, will present certain modes, according as the sensibility, the villous membrane, or the follicular apparatus, is prominently affected. Those states of disease which are generally consequent upon dyspepsia, although sometimes appearing independently of it, and which have been classed by some writers as severer forms of this complaint, will be found under the heads referred to above.

5. I. Description. — i. Simple Asthenic Dyspepsia; — *Stomachi Resolutio*, Celsus, — *Frigiditas Stomachi*, Prosper Alpinus, — *Dyspepsia Idiopathica*, Cullen, — *First Stage of Indigestion*, W. Philip, — *Atonic Gastric Dyspepsia*, T. J. Todd, — *Dyspepsia per Asthenie de l'Estomac*, Andral, — *Dyspepsia Apyrétique As-*

thénique, **BROUSSAIS**; — is *characterised* chiefly by a sense of distention of the stomach, by acrid or acid eructations, and flatulence, soon after a meal; by loss of appetite, or loathing of food, and occasionally by nausea. These symptoms, however, vary with the nature and quantity of the food. Heartburn, nidorous or putrescent eructations, and a feeling of weight or oppression at the epigastrium, are generally present after a very full meal, particularly of fat, oily, or rich meats. The tongue is pale, flabby, whitish, slimy or coated, and often indented by the teeth; the bowels are costive, sometimes irregular; the urine is pale, copious, and occasionally deficient of urea, or contains albumen; the pulse is softer, weaker, and often slower than natural; the temperature is diminished, or irregularly distributed, the extremities being cold, and the surface pale, or flaccid; the eyes are languid, and the physical and mental powers deficient in vivacity and energy. The symptoms, however, vary much in grouping and intensity with the kind, quantity of the solid and fluid ingested, with the temperament and constitution, and with the manner in which associated viscera are sympathetically affected. In some cases, they are gradually and very slowly developed by the continued operation of the causes; in others, they are more rapidly or suddenly induced by errors in diet, or by other powerful circumstances.

6. *A.* The latter, or the *more acute* and *sudden attacks of indigestion*, are generally consequent upon some manifest cause, particularly an overloaded state of the stomach, — and is identical with the *cruditas* of the ancients, and the *embarras gastrique* of the French. — It may occur, however, from substances which disorder the organic sensibility of the viscus, or from other causes. When it proceeds from this source, the symptoms soon follow a full meal, or appear in the morning. The patient experiences various uneasy or even painful sensations, with oppression or weight at the epigastrium, and heart-burn. These often extend to the pharynx. The tongue becomes dry, clammy or loaded, and the taste is lost or perverted. Rancid, oily, indigested, or acid substances are eructated or brought off the stomach, without nausea or retching. There are generally headach and languor. If nausea and vomiting take place, the contents of the stomach are thrown up, either partially or altogether undigested, with a ropy phlegm. Where vomiting does not occur, a sense of irritation or constriction of the fauces and pharynx, with a copious secretion of a watery fluid, and pains in the stomach, are often present. The appetite is abolished, or savoury articles of food are only relished. When the fit of indigestion occurs during the night, the patient experiences frightful dreams, or the nightmare, or spasmodic twitchings of the limbs, or severe pains in the stomach or bowels, or wakens with severe headach. The pulse is weak, languid, or soft; the skin cool and moist, and the extremities cold. Frequently chills, horripilations, formications, or even slight shudderings occur. Various sympathetic affections often attend this state of dyspepsia, particularly headach, as described in that article, impaired or indistinct vision; muscæ volitantes, noises in the ears, and dullness of *hearing;* disorder or impairment of the senses of taste and smell, palpitations, and vertigo, colicky pains in the abdomen, costiveness, &c.

7. An attack of dyspepsia in an acute or sudden form seldom appears, unless from the causes just alluded to. But it may proceed, particularly in delicate persons or females, from other causes, as powerful mental impressions, long fasting, or deprivation of wonted stimuli. In such cases, vomitings, or even retchings, rarely occur; but nausea or disgust at food, giddiness, headach, faintness, sinking or pain at the epigastrium, costiveness, palor and coldness of the surface, and inactivity, with irritability of temper, with some of the other symptoms already noticed, are commonly complained of. — These *acute* attacks are liable to pass into the more *confirmed* or chronic state of the complaint, next to be described, particularly when they recur frequently, or are neglected.

8. *B.* The *confirmed* or chronic form of dyspepsia may take place gradually or slowly, or as a consequence of the foregoing. In the former case, it is almost imperceptible in its progress, but it generally commences with symptoms of general, as well as local, debility. All the physical and mental functions betray more or less inactivity. The sleep is disturbed or unrefreshing, sometimes heavy or prolonged. The appetite in the morning is impaired and capricious, savoury articles being chiefly relished, and a sense of soreness or relaxation in the throat is often complained of. A full meal is followed by heaviness, yawnings, stretchings, and an almost irresistible disposition to sleep, by sense of fullness, weight, flatulence, or by rancid or acrid eructations, &c. As the disorder continues, the appetite is more impaired and more capricious. The bowels become costive or irregular; the discharges being scanty, offensive, discoloured, or more copious or frequent, and sometimes containing imperfectly digested portions of food. The biliary secretion is either insufficient or disordered. Perspirations are copious on exertion, often offensive, and quickly discolour the linen. Flatulence is troublesome, particularly when the stomach is empty; the mouth is clammy, and the tongue loaded or furred, especially in the morning. The countenance becomes pale or unhealthy; and the body occasionally enlarges about the trunk or abdomen. Vertigo, loss of memory, lowness of spirits, apathy, indifference; and numerous associated and sympathetic disorders supervene, according as the asthenia of the stomach extends to the duodenum and intestinal canal, or to the secreting collatitious viscera. In many cases, the affection extends along the æsophagus to the pharynx and fauces, occasioning the slightest forms of angina, or simple relaxation of the uvula.

9. As dyspepsia becomes confirmed, various additional sympathetic affections appear. Indeed there is scarcely a viscus, that may not betray disorder. Irritation about the larynx, chronic cough, particularly in the morning; huskiness of the voice, or hoarseness; copious perspirations, and eruptions on the skin; dry and parched state of the hair, or morbid condition of the cuticle and of the nails; great sensibility of cold, and also of heat; are very commonly observed. Shortness of breath on slight exertion; palpitation of the heart; intermissions and irregularity of the pulse; and other sympathetic disorders about to be noticed, often also appear. This variety of indi-

gestion, when neglected, or when its causes continue in operation, sooner or later passes into one or other of the forms of the variety, next to be described.

10. ii. INDIGESTION WITH VASCULAR ERETHISM, —*Irritative Dyspepsia; Cardialgia Inflammatoria*, SAUVAGES, — *Gatsrite Chronique*, BROUSSAIS, — *Second Stage of Indigestion*, W. PHILIP, — *Inflammatory Gastric Dyspepsia*, T. J. TODD, — is *characterised* chiefly by slow and painful digestion, a sense of heat and discomfort at the epigastrium, increased by food and by pressure, with thirst, dryness of the mouth and fauces, redness of the edges and point of the tongue, whilst the middle and root are white, loaded, or furred; costiveness, high-coloured urine, partially increased temperature and dryness of the skin, and a more frequent and sharp pulse than natural. It offers several *grades* of severity and various *modes*, according to the exciting cause, the temperament of the patient, and to the manner in which the organic sensibility and contractility, the secretions and associated viscera, are individually implicated. It may appear suddenly in an acute form, when the cause has been active, or gradually and slowly, either primarily, or consecutively upon the variety already described.

11. *a.* In the *slighter states* of irritative dyspepsia, the appetite is often increased, occasionally ravenous, in some instances impaired; thirst is generally present, particularly in the evening. The extremities are often cold; but burning or heat of the soles of the feet and palms of the hand frequently occur, particularly in warm or temperate weather. The point and edges of the tongue are red, the papillæ raised or excited, and the root more or less loaded; the bowels are confined, and the stools dry and scanty. The pulse is somewhat excited, especially in the evening, and rather sharp than hard or contracted. Headach, sometimes with slight redness of the conjunctiva and contraction of the pupils, heaviness, unsound sleep, unpleasant dreams, and a feeling of fatigue and lassitude upon waking, are generally present. The symptoms referred directly to the stomach, at first, are often not more severe in this, than in the preceding, variety; and pain, with tenderness on pressure, is not more frequently complained of. As the complaint, however, becomes more chronic, a burning pain is felt at the stomach, and is increased by a full meal and by pressure. Great discomfort and a sense of a load are referred to the region of this organ. Fulness or distension at the epigastrium, often extending to one or both hypochondria, is usually present. When heartburn occurs, it is characterised by a sense of heat or burning, and attended by redness and soreness of the fauces and pharynx. The tongue and throat are frequently dry, and the voice soon becomes husky on speaking, or on exerting it. Small vesications occasionally appear on the sides and points of the tongue, and more rarely excoriations on the fauces. In protracted cases, the tongue is often smooth, sometimes slightly fissured or chapped, or lobulated, or even glossy. Pain is felt in the left shoulder, or in the left hypochondrium, extending to the shoulder blade, or between the scapulæ, and beneath the sternum. Severe headach; irritability of temper; depression of spirits; impaired appetite; palpitations; a harsh, dry state of the skin, frequently with scaly eruptions; occasional bursts of perspirations during sleep; inability to lie on the left side; burning heat in the palms of the hands and soles of the feet; increased acuteness of the senses, or obscuration of certain of them; and a morbid state of all the excretions, severally appear, and often divert the patient's and practitioner's attention from the source of disorder. In some cases pain, often increased by flatulence, shoots through the hypochondria and chest, and a symptomatic cough, with slight greyish expectoration in the morning, is excited, owing to nervous connection, and to the extension of irritation to the pharynx and top of the larynx. In these, pectoral disease is sometimes suspected; and inflammatory irritation of the larynx may be actually thereby occasioned.

12. *b.* In the more *severe* or *acute attacks* of this variety of indigestion, particularly when produced by hurtful or indigestible food, or stimulating liquors, there is a total and sudden loss of appetite, with nausea, retchings, or full vomiting, increased by, or instantly following, the ingestion of substances into the stomach. Occasionally, the contents of the organ are regurgitated without effort or nausea, but with pain or a sense of constriction at the epigastrium and hypochondria. The pulse, is at times, but little affected; at others, quick and sharp, and the skin is harsh and hot; but perspirations break out when free vomitings are induced. There is always thirst; pain, or a sense of burning, of scalding, or of soreness is generally felt in the stomach, and it often extends, in the course of the œsophagus, to the throat; giving rise to a similar symptomatic affection of this part, and of the larynx and chest, as just noticed (§ 11.). In rare instances, however, where the retchings and vomitings are frequent and severe, but little pain, and no tenderness in the epigastrium are present, or much less than the severity of the symptoms indicates. The copious discharge from the mucous follicles and exhalents of the villous coat in these cases, removes the congestion of vessels, or the morbid conditions productive of pain and tenderness in other cases. But the symptoms vary remarkably with the exciting cause, with the temperament and disposition of the patient, and with the previous disorder and existing state of the collatitious viscera.

13. *c.* In the *aged*, or in *young persons of a phlegmatic temperament*, and in *cold* or *damp climates* and *seasons*, irritative dyspepsia assumes a form which has been denominated *Anorexia pituitosa, Anorexia Catarrhalis, Catarrh of the Stomach*, &c., by various writers. Dr. TODD has called it *Follicular Gastric Dyspepsia;* and most probably it proceeds from an inordinate and morbid secretion from the follicles of the stomach, that irritates the organ; but he has improperly confounded it with *Pyrosis*, which it closely resembles. It is characterised by an aching pain, by gnawing, or by a sensation of cramp, weight and uneasiness, or soreness, felt chiefly in the morning, when the stomach is empty, by loss of appetite, nausea, and sometimes by vomiting of a ropy, transparent, glairy, and tasteless fluid. It is often complicated with, or consequent upon, severe catarrhal affections of aged or phlegmatic persons, and is not infrequent in rheumatic constitutions, after errors in diet, and the use of indigestible, rich, or incongruous articles of food or drink. In this case, it usually occurs in the night and fol-

lowing morning. Along with indigested substances, a very large quantity of this colourless glairy matter is thrown up, and often continues to be ejected for a considerable time afterwards. M. ANDRAL has seen it thrown off in very large quantities, independently of the irritation of offending matters; but these matters are more commonly concerned in keeping up the morbid secretion. In most of the cases I have seen, the pulse was soft, languid, sometimes sharp during the attack, which was attended by a foul, loaded, or sodden state of the tongue, a warm perspirable surface, or free perspiration, much depression of nervous power, and constipation; but there was little or no thirst, nor tenderness or increase of pain on moderate pressure of the region of the stomach. Flatulence, eructations of an insipid or slightly acid fluid, a copious flow of saliva from the mouth, or of a watery fluid from the pharynx, and oppression or distension of the stomach, although pain is much abated, after eating, generally accompany the disorder. This form of irritative dyspepsia is often preceded or attended by severe catarrhs, by dyspnœa, or humoral asthma, or by rheumatic affections; and it is most common in cold and wet seasons, when these are prevalent. In its slighter or less acute states, or when appearing independently of over-distention or irritation of the stomach by bulky or indigestible substances, the pulse is usually slow or soft, the extremities cold, the evacuations scanty or mucous, and the tongue white, sodden, or loaded. As Dr. TODD remarks, there is a frequent desire to take food, with thirst, and, as the disease continues, there is wasting of the flesh. The uneasiness caused by the laborious digestion subsides as the process is finished; but before the time of taking food arrives, the stomach becomes irritated by its own secretion, which produces all the inconvenience of a foreign indigestible substance in that organ; such as a sense of sinking, of dragging, of nausea, faintness, gnawing, or erosion, which are again, for a time, relieved by the taking of food. (See art. PYROSIS.)

14. iii. OF CERTAIN SYMPTOMS OF INDIGESTION. — *A. Cardialgia*, or *Heartburn*, presents itself in two forms, each of which assumes various grades of severity. It is generally attended by *acid* or acrid eructations, exciting irritation in the throat and fauces. The acidity of the eructated matters is often remarkable, occasioning the most unpleasant sensations in the mouth and pharynx, with a copious flow of fluid from those parts. The matters brought up from the stomach are sometimes rancid and *alkaline*, particularly after a full meal of rich or fat animal food. In this case, a feeling of disgust is excited on each eructation, and large quantities are thus thrown off, or regurgitated from the stomach, without either nausea or retching. In either form, unpleasant gnawing, burning pain, and tenderness, are felt at the epigastrium, with distention, extending to the hypochondria, and with tightness or oppression in the chest. Cardialgia chiefly occurs during the period of digestion, but sometimes not until an advanced stage of the process. It may be mild, and consist simply of uneasy sensation, gnawing, or burning at the cardia, sometimes with slight faintness or flatulence; or it may be severe, the uneasiness extending over the region of the stomach, attended by depression, anxiety of countenance, and faintness. This latter state has been denominated *sinking heartburn*. It is only when cardialgia is severe, that it is accompanied with frequent and copious, rancid, alkaline or septic eructations.

15. *B. Of the Evacuations, &c.*—*a*. The *stools* furnish comparatively little information in dyspeptic ailments, when only those procured by an active purgative are examined. They are most commonly scanty, dry, and deficient in healthy odour and colour, especially in the asthenic and simple states of the complaint. In the irritative states, the discoloration is often greater, and they are occasionally mucous or watery, particularly when irritation extends along the alimentary canal. But in either variety, they vary remarkably in colour, consistence, and character; being either dry, pultaceous, slimy, scybalous, mucous, bilious, clayey, whitish, or yeasty, and sometimes presenting several of these appearances at the same time. The calls to evacuation are commonly rare or delayed, but they are occasionally frequent and inefficient. It is chiefly when torpid or disordered function of the liver, duodenum, or intestinal canal, is associated with indigestion, that the states of the evacuations described by Dr. W. PHILIP are met with; for these states, as Dr. J. JOHNSON justly contends, are not common in the simpler forms of the complaint. "The alvine discharge," the former writer remarks, "sometimes chiefly consists of bile; its colour at other times is too light, more frequently too dark, and occasionally almost black; at different times it assumes various hues, inclining to green or to blue; and sometimes it is mixed with, and now and then almost wholly consists of, undigested bits of food." When there is much straining, it often contains mucus, sometimes in distinct masses, or substances resembling bits of membrane. "It frequently separates from the canal with more difficulty then usual, and leaves a feeling of the bowels not having been completely emptied."

16. *b*. The *urine* of a person in good health is perfectly clear and limpid when passed, and continues so for some time after it cools, being more or less deep in colour, according as its ingredients are concentrated or diluted. But it has been satisfactorily shown, that when acidity is prevalent in the stomach and digestive canal, or when the usual acid secretion of the skin is impeded or suppressed, the urine, after standing for some time, deposits a reddish substance, which is found to be a coating of lithic acid, the supernatant fluid still remaining clear; but when an opposite condition to this exists in the digestive organs, the contents of the stomach being alkaline or devoid of their proper acidity, and when the function of the skin is unusually excited, the urine becomes turbid, and a whitish, or purulent white, sediment is observed, consisting of lithate of ammonia, or of an amorphous deposit of phosphates and lithates. If irritation or inflammatory affection of the stomach is present, this fluid is scanty and high-coloured. In irritability of the organ, it is often pale, limpid, and very copious. In several states of indigestion, it occasions smarting in its passage, owing to the unusual abundance of urea. Dr. PROUT observes, that in one or two cases of obstinate dyspepsia, he has seen the urine not only passed of a bright pink colour, but remain so on cooling, without depositing any sediment; and he considers this pink colour to proceed from the large quantity of purpurate of ammonia present, which, from there being no lithate of ammonia with which it might be combined, was necessarily held in solution.

17. *c. Pain and tenderness at the epigastrium* and region of the stomach have been much insisted upon by Dr. W. Philip, as indicative of the more inflammatory states of dyspepsia. But as I have shown elsewhere (see Stomach — *Morbid Sensibility of*), the most severe pains in this organ are often felt without any inflammatory disposition. Tenderness upon pressure is a very common symptom in the slight or more functional states of indigestion, as well as in the severe or more inflammatory, especially in thin and delicate persons. It is seldom wanting in irritative dyspepsia. The tenderness is often connected with *fulness* in this region, and also in the hypochondria. But this latter symptom is generally owing to the distention caused by flatus, and by feculent and flatulent collections in the colon. When emaciation takes place in protracted cases, the fulness becomes more apparent.

18. *d.* The *pulse*, in dyspepsia, is extremely various, but it is most commonly as I have described it. During the digestion of a full meal, it is usually accelerated, and somewhat harder or sharper than usual. The hardness insisted on by Dr. W. Philip, as indicative of the passage of functional into inflammatory dyspepsia, is seldom present. Sharpness and quickness are more frequently observed, and are symptoms of irritation rather than of inflammation. The febrile symptoms occasionally occurring, with soreness of the throat, high-coloured urine, and impaired secretions, are more probably occasioned by the former, than by the latter pathological state.

19. *C. Of the states of the associated viscera in dyspepsia.* — It is obvious that indigestion will vary in form and severity, with the concomitance of disorder in any of the other digestive organs. — The functions of the Duodenum may be deranged, as shown in that article; and, in this case, dyspepsia will present more or less of the characters there described (§ 2.). Other parts of the digestive canal may be deranged, the affection consisting either in impairment of function, or in nervous or vascular irritation, and being limited to the small intestines, or to the large bowels, or even to one only of the latter. (See arts. Cœcum and Colon.) In such cases, the physician will be guided by the state of the evacuations, and by the symptoms detected on a careful examination of the abdomen. — It is not improbable that the pancreatic secretion becomes disordered, particularly in protracted cases; but of this sufficient proofs are seldom furnished: at best it can be only a probable inference. That this secretion may be diminished is not unlikely, inasmuch as there is sufficient evidence of the *biliary secretion* being deficient, retained, and altered, especially in the chronic states of indigestion; and it is reasonable to infer, that, when one of the organs deriving influence from the same part of the nervous system is impaired in its functions, the other organs thus associated, as well as otherwise anatomically connected, will be similarly, if not coordinately, affected. Indeed, every experienced practitioner must have noticed a more or less remarkable deficiency, or other disorder of the bile in dyspepsia; and not only of it, but also of the other secretions poured into the intestinal canal. That the disorder originally induced in the stomach, often extends to the other digestive organs, owing to various concomitant or consecutive circumstances, cannot be doubted. It may be even apprehended, that the consecutive disorder will become the most serious in its nature and consequences, when these circumstances are frequent or continued in their operation; and that it will thereby obscure or mask the original affection. In many cases of dyspepsia, the functions of the biliary apparatus are impaired, in respect, not only of the quantity, but also of the qualities or properties of the secretion. In some, more or less of retention or obstruction of bile actually takes place, as shown by the state of the stools, rather than by the colour of the surface of the body. The remora of bile, also, in the biliary ducts and gall bladder, arising from impaired function of the stomach and torpor of the liver, will further increase the morbid state of the evacuations.

20. *D. Sympathetic affections of various organs.* — Whilst an immense number of diseases originate in neglected or protracted indigestion, various disorders are entirely sympathetic of it. Diseases of the urinary organs, of the liver and bowels, gout, rheumatism, various painful, neuralgic, and nervous affections, eruptions on the skin, disorders of the catamenia, and many others, often thus arise. Dr. Webster, in a treatise published in 1793, endeavoured to show this, before the appearance of the writings of Mr. Abernethy on the subject; but it had not been altogether neglected in the works of Whytt and others. This excellent author very justly remarks, that a delicate state of the first passages, or an unnatural sensibility of their nerves, not only disposes to many complaints in those parts, but the whole nervous system is thereby rendered more liable to be affected by the slightest causes. "Faintings, tremors, palpitations of the heart, convulsive motions, and great fearfulness, may be often owing more to the infirm state of the first passages, than to any fault either in the brain or heart. The powers which the alimentary canal, when its nerves are disagreeably affected, must have in producing disorders in the most distant parts of the body, cannot be doubted by those who attend to that wonderful and widely-extended sympathy, which obtains between it and almost the whole system."

21. *a.* The brain and organs of sense are often much affected by indigestion. *Headach* is one of the most common and severe affections, sympathetically excited by this complaint; but it has received sufficient consideration in the article on its different forms. The manifestations of *mind*, both intellectual and moral, are also often more or less disordered, although but slightly or imperceptibly. Memory is somewhat impaired; attention is unsteady and cannot be long continued; the disposition is more fickle, and the temper more irritable than natural. There are often confusion of thought, or of ideas, lowness of spirits, despondency, and vertigo, particularly in severe or protracted cases. M. Broussais has argued with much apparent justice, that the functional disorder, thus sympathetically induced in the brain, may, by its frequency or continuance, pass into organic change; and several recent writers in this country have adopted the opinion.

22. *b.* The *organs of sense* are not less liable to sympathetic disorder. — The *sight* becomes weak and indistinct; the eyes impatient of light or irritable; and specks or muscæ volitantes appear in the

axis of vision. — *Hearing* is frequently impaired, often from weakness of the nerves; but sometimes in consequence of the erythematic redness and inflammatory irritation, symptomatically produced in the throat, having extended along the Eustachian tube to the internal ear; or having caused obstruction of this canal. Noises in the ear are usually present in these cases; and these, as well as the hearing, depend much upon, and vary with, the state of the stomach. Care should be taken, however, not to impute affections of the head and of the senses, depending upon disease within the cranium, to disorder of the digestive organs. The disorders of these parts, arising from the stomach and other digestive viscera, disappear or are mitigated by wholesome food and drink, taken in moderate quantity; but when they proceed from the brain, they are aggravated, or at least, not mitigated, by the usual ingesta.

23. *c.* In the article FLATULENCE, I have shown the effect produced upon the actions of the *heart* by this, and other causes of distention of the digestive tube. Palpitations, and irregularity and intermissions of the pulse very often proceed from dyspepsia, particularly when the functions of the liver and of the intestinal canal are also disordered. In such cases, the morbid sounds of the heart are usually wanting, unless in some cases of severe palpitation, when a slight bellows sound is heard. The functional disorder, when frequent or protracted, may be followed by dilatation or some other organic change. When structural lesion already exists in this organ, the symptoms are much increased by indigestion, and by concomitant disorder of the liver. It should, however, be recollected, that lesions of the heart often occasion congestions of the liver and dyspeptic affections; and always aggravate them, where they already exist.

24. *d.* The influence of dyspeptic complaints in producing *affections of the lungs*, was contended for by Dr. W. PHILIP, doubted by Dr. PARIS, but admitted, in a limited sense, by Dr. J. JOHNSON, and some others. The choice Dr. PHILIP made of the term "*dyspeptic phthisis*," was certainly not fortunate, inasmuch as its meaning is equivocal. In protracted dyspepsia, and particularly when the liver becomes congested, or otherwise disordered, the respiratory organs often also are affected; the disorder of the digestive viscera both predisposing to affections of the respiratory passages, and occasionally more directly causing them. The irritation excited in the œsophagus, pharynx, and top of the larynx, by the affection of the stomach, is sometimes propagated along the air passages; and if, at the same time, the stomach is frequently distended and the liver congested, so as to impede the circulation through the lungs, disease of this latter probably will often be induced, especially if latent tubercles, or some other states of predisposition, exist. Besides, the debility caused by protracted disorder of the digestive organs often calls latent tubercles into activity, or rapidly developes them; and it may even be suspected that the impaired nutrition, consequent upon the debility and protracted disorder of the organs of supply, will sometimes even give rise to tubercular productions, where they did not previously exist even in a rudimental state.

26. iv. THE CONSEQUENCES AND TERMINATIONS OF INDIGESTION have been partially alluded to (§ 19, 20.); but they require a more particular notice. (*a*) Dyspepsia may terminate in a restoration of the healthy function of digestion; — (*b*) It may pass into more severe functional or structural disease of the stomach; — (*c*) It may superinduce disease of the liver, bowels, and other collatitious organs; — (*d*) It may give rise to affections of remote organs or parts; — (*e*) and lastly, it may alter the constitution of the circulating fluids, originate diseased secretions and depositions, and generate a morbid diathesis of the system, occasioning several serious consitutional maladies. These consequences will, however, depend much on the exciting causes, the predisposition, the temperament, the habit of body, and other circumstances proper to the person affected.

27. *a.* A termination in restoration of healthy digestion seldom takes place, or if it take place, it is rarely permanent, unless the predisposing and exciting causes are avoided. Many of those causes originate in those propensities, desires, and passions, which are controlled with the greatest difficulty; and several of them depend upon habits, which require the utmost force of character to relinquish. Hence the want of success so often experienced in the treatment of dyspeptic complaints, and the dissatisfaction evinced by those who run from one physician to another, unreasonably expecting immediate or permanent relief, still desiring to indulge the senses — to gratify the propensities and desires, natural or acquired, without paying the penalties thereby incurred. Hence, also, the frequency of the serious consequences of severe or neglected dyspepsia about to be noticed.

28. *b.* The forms of indigestion already described, from neglect or the continuance of their causes, may pass into the more severe affections of the stomach. In some instances, the most violent *gastrodynia* or gastralgia supervenes on them. (See STOMACH—*Painful Affections of*.) In others, PYROSIS follows the form of irritative dyspepsia attended by the rejection of a glairy fluid, (§ 13.) and seems to be an extreme condition of the same complaint with modifications depending upon peculiarities of constitution and of functional lesion. In some cases, VOMITING (see that article) of a severer or more prolonged character than that occasionally taking place in dyspepsia, occurs, even independently, although more frequently in consequence, of structural change of either the stomach or some other organ. In the latter case, the source of mischief may be in the liver, or in the brain, or even in the kidneys, or uterus. More rarely neglected cardialgia or other dyspeptic states pass into partial or complete RUMINATION, (see that article), particularly when the meals are taken hurriedly, in large quantity, and insufficiently masticated (see AUTHOR, in *Lond. Med. and Phys. Journ.* for May, 1821, p. 362.). Neglected dyspepsia is very frequently followed by inflammatory action, and its consequences in the villous coat of the stomach (see STOMACH —*Inflammation and Organic Lesion of*). This result, I am convinced would more frequently take place, and when it did occur, would lead to still more serious effects, but for the circumstance of the secretions from the villous coat favouring resolution by unloading the capillary vessels, and for the want of appetite and nausea attending inflammatory action, preventing the ingestion of substances calculated to keep up the morbid action.

28. *c.* The supervention of disease, functional or structural, in collatitious viscera, in the course even of the more simple and slight forms of indigestion, is so common, that the attention should never be withdrawn from it in practice. There are few cases of dyspepsia, in which the functions of the Liver and Duodenum (see those articles) are not more or less disturbed. The *liver* becomes torpid and congested, and sometimes more or less tumid, from either congestion in its vessels, or accumulations of bile in the ducts; this secretion being often inspissated from absorption, during its remora, of its more watery part. It then either obstructs, irritates, or otherwise disorders the canals along which it passes (see art. Gall Bladder and Ducts), and affects even the substance of the liver itself, which ultimately becomes inflamed, and gradually and variously changed. In protracted or severe cases of indigestion, other organs also become disordered, especially the bowels; *constipation*, *colic*, or *diarrhœa*, in some one or other of their forms, frequently occurring, particularly when irritation of the digestive mucous surface is induced, and when the secretions, poured into the intestines, are deranged.

29. *d.* Affections of remote organs, sympathetically produced by dyspepsia, have been already noticed (§ 20.), but there are others which arise from this complaint, rather by a succession of morbid changes, than by any sympathy or consent of parts. When protracted or severe indigestion gives rise to an imperfectly elaborated chyle; or when the impaired organic nervous energy, which is chiefly manifested in the functions of the stomach in dyspepsia, extends also to the circulating, assimilating, and excreting organs; affections of the kidneys, and urinary bladder, in connection with a morbid state of the urinary secretion, frequently take place. Hence the formation of sabulous matter or gravel in the urine, and of calculi in the kidneys and bladder; and even the production of diabetes, and of slighter disorders of the excretion of urine. In females, dyspepsia not unfrequently occasions difficult, too frequent, or delayed or irregular menstruation, hysteria, and painful affections of the spinal nerves in some portions or other of their distribution, with tenderness in the dorsal spine. In both sexes, cutaneous eruptions either originate in, or are perpetuated by, dyspeptic disorders, and by the state of the circulating fluids, and of the cutaneous exhalation consequent upon them. A due recognition and estimation of these connections of disorder are of the utmost importance in practice.

30. *e.* There is every reason to infer, that the pathological conditions, of which dyspepsia is an early and important indication, by altering the functions of assimilation and secretion, and weakening the processes of depuration, may give rise to a state of the circulation, productive of painful affections, or of unnatural formations and depositions in weak or predisposed parts; or in other words, to a truly morbid diathesis, or constitutional derangement. Hence the frequency of rheumatism, of neuralgic or painful affections, of urinary calculi and gravel, and especially of gout, after protracted or severe indigestion.

31. II. Causes.—*A. Predisposing.*—Indigestion, although not confined to any period of life, occurs most commonly between the ages of twenty and forty-five; and in *its simple form* more frequently in the female, than in the male sex. The upper classes of society and the middle ranks of life are most subject to this variety of the complaint. It is more prevalent in cold and temperate, than in warm climates, and in the winter than in the summer; but whatever may be the temperature of the climate or of the season, damp weather, and a moist atmosphere, may be regarded as among its most active predisposing causes. The predisposition to this disorder is sometimes hereditary, particularly in persons of a weak relaxed fibre, with high nervous susceptibility, and general debility of constitution. Those in whom the functions of the stomach are naturally weak and feebly performed, the circulation languid, the temperature of the extremities below the natural standard, and the secretions generally disordered, or more abundant than usual, are also constitutionally predisposed to dyspepsia. Sedentary occupations, especially when carried on in close rooms and factories, indolent habits either of body or mind, long and intense study, insufficient exercise in the open air, addiction to debilitating excesses and injurious indulgences, luxurious modes of living, indulgence in sleep or in bed, breathing impure air and confinement to close or ill-ventilated apartments, remarkably predispose to this complaint. In persons thus predisposed, the slightest excess or irregularity, or the most trivial exciting cause, is often sufficient to bring on an attack of indigestion; whilst a repetition of such causes, or long exposure to their action, in those of a stronger habit and more vigorous constitution, cannot fail to have a similar effect.

32. *B. The exciting causes* are divisible into two classes: — (*a*) Those which operate immediately or directly upon the stomach itself; and (*b*) Those which influence this organ through the medium of other parts. — (*a*) The causes, which affect the stomach itself, act either by diminishing or otherwise vitiating its secretions, so that the due change is no longer effected in the food; or by debilitating its muscular power, so that the aliment, although it may have been properly acted upon by the gastric juice, is not propelled into the duodenum with the natural ease and rapidity. As the admixture of the food with the gastric juice, and the passage of the chyme into the duodenum can only be accomplished by the due contraction of the muscular fibres of the stomach, it is evident that, whatever tends to weaken or to impede this action, will at once be followed by oppression or distention of the organ. In this class of agents may be included narcotics, taken habitually or in excess, as opium, henbane, conium, digitalis, &c., indulgence in ardent spirits, or intoxicating liquors, and the constant or frequent use of the preparations of ammonia, of lavender, and of other aromatic spirits. But the most common causes of indigestion are, irregularity and want of due caution in diet, whether as regards the quantity, or the quality and congruity of the food, or the periods at which it is taken, and the use of tobacco in any of the modes in which this noxious substance is so generally employed.

33. A want of due relation between the state and powers of the digestive organs, and the substances upon which they are required to exercise their functions, is a very frequent cause of this complaint; for whether the stomach be distended by

an unusual quantity of food; or whether its secretion be compelled to act upon substances which are inappropriate, or to which it is unaccustomed, the function of the organ will be equally impeded; and if the exciting cause be powerful, or continue in operation, digestion will be altogether suspended. Hard and indigestible articles of food must therefore be productive of this disorder; and hence its frequency among the peasantry and lower orders. Heating and highly-seasoned articles of food, hot dishes, and condiments, mushrooms, shell-fish, melons, cucumbers, nuts, and similar substances; raw, stale, or unripe fruit; rich articles of confectionary; acid, iced, or sweet fluids, especially when taken during the process of digestion; large quantities of cold or of warm fluids, as of tea, relaxing slops, &c.; and the habitual use of malt liquor, are among the most common causes of indigestion. The kind of aliment also exerts no small influence, even in mechanically distending, and thereby weakening the stomach; for as most of the articles of food, when received into the organ, seem to swell in a greater or less degree, a bulky meal, particularly of solid or pultaceous or vegetable substances, will not a little contribute to this effect. To the above causes may be added, irregularity in the period between the times of taking food, hasty or imperfect mastication, frequent interruption or talking during the progress of eating, the omission of an accustomed meal, abstinence or long fasting,—hence its frequent occurrence during the fasts of the Catholic church, and among the Brahmins, Fakirs, &c., in India,—a sudden change in diet from animal to vegetable food, and from substances of a succulent and refreshing, to those of a dry and heating nature, and severe and repeated vomiting. All these tend, in a greater or less degree, to debilitate the muscular fibres of the stomach; to produce a deficiency of gastric secretion, or a secretion vitiated in its properties; and to irritate the villous coat of the organ.

34. *b.* Amongst those causes which operate on the stomach through the medium of other parts, may be classed those mental emotions, which depress nervous power, or otherwise disorder its manifestations. A due secretion of the gastric fluid depends much on the state of nervous influence; for a deficiency of the latter impedes or lessens the former. Any sudden intelligence, a violent fit of passion, or of great joy, sometimes instantly brings on an attack of indigestion. Grief, anxiety, envy, jealousy, indulgence in tender feelings, repeated disappointment, reverses of fortune, night watching, &c., more slowly, but more certainly, exert a similar influence. Whatever exhausts the body and lowers the constitutional powers, exerts a correlative effect on the digestive functions, as venesections improperly adopted, or soon after a meal; protracted hæmorrhages; menorrhagia; leucorrhea; venereal excesses; seminal weakness; and exhausting discharges of any kind. In persons particularly of a weak and delicate constitution, indigestion is easily induced by change of weather, by exposure to the night air or to cold and humidity, by cold extremities, by a low temperature when the body is quiescent, as when travelling in an open carriage or on the outside of stages, by a fatiguing journey, by damp residences, and similar circumstances. Whatever exerts a depressing effect on the organic nervous power, or on any of the internal viscera, will also lower the function of the stomach, as large doses of calomel, or too long a continuance of this medicine, irritating and drastic purgatives, &c. Dyspepsia may be brought on, also, by the suppression of the natural and the accustomed discharges, or by the retropulsion of cutaneous eruptions, &c. It also not unfrequently accompanies catarrhs, rheumatism, and diseases of the thoracic viscera; it is a necessary consequence of disorder of any other of the abdominal organs; and it precedes and attends the various states of gout, &c.

35. *C. The irritative states of dyspepsia* are more frequently met with in the male than in the female sex, and are very prevalent in the southern countries of Europe, and amongst Europeans resident in tropical regions. They are common in those warm climates in which the air is dry, and the temperature subject to frequent and sudden variations; but the causes acting directly on the stomach are often frequent and influential in those countries. In warm climates, the modes of living — the diet and regimen of Europeans are extremely prejudicial to the digestive functions, as shown by Mr. Annesley, and the Author. (*Researches on the Diseases of India and of Warm Climates, generally, &c.*, 4to. vol. i. p. 226.) The quantity and nature of the food and drink usually taken excite and irritate the stomach, liver, and intestinal canal, and exhaust their functions; the states of indigestion thus induced soon passing into inflammation, or into organic changes, if neglected or injudiciously treated.

36. The irritative states of dyspepsia are, however, by no means uncommon in this country, in hot seasons, and even in very cold weather, and during the prevalence of severe or long continued frosts, accompanied by north-easterly winds. They affect chiefly persons of a sanguine and bilious temperament, and of plethoric habit; and in them, especially, are sometimes produced by checked perspiration, by the suppression of accustomed discharges, as of hæmorrhoids, of leucorrhea, of the catamenia, &c., by the drying up of ulcers, and by the repulsion of cutaneous eruptions. They are, however, more commonly occasioned by the abuse of stimulants, as highly-seasoned and rich food, and by addiction to spirituous and intoxicating liquors, and to opium. These states of indigestion are not so often consequent upon errors in diet, as the other forms of the complaint; but they are most frequently met with in the habitual drunkard. They may be induced by change of diet, or change of residence, or climate, and hence their greater prevalence during spring and autumn; by stimulating medicines, as a long continuance of the use of cubebs and copaiba for gonorrhea; by drastic and irritating purgatives; by powerful or repeated emetics; by tonic, stomachic, and aromatic spirits or tinctures, taken in too large doses, or on improper occasions; by hot spices and pickles, particularly cayenne pepper, capsicums, &c.; by the frequent use of mercurial and of heating medicines; by drinking cold and acid fluids after violent exercise, or whilst the body is perspiring; and by various noxious articles, used either as food or drink, or which give rise to incongruous mixtures in the stomach.

37. III. Pathology. — Indigestion manifestly proceeds from the following *conditions* of the sto-

mach and related organs, either of which may be somewhat more prominent than the rest: — 1. Impaired organic nervous power of the stomach. 2. A deficient or disordered state of the gastric juice, or a want of a due relation between the quantity and nature of this fluid and the ingesta. 3. Impaired absorbing power of the stomach, rendering the digestion of the fluid ingesta more or less difficult, and weakening the gastric fluid. 4. Diminished muscular energy of the stomach; the motions and tonic vermicular actions of the organ being weakened, and the admixture of the gastric juice with the ingesta being thereby impeded or delayed.* These pathological conditions may be *primary*, or they may be *consecutive* upon disease of the brain, of

---

* As Dr. COMBE observes, the *first* requisite to digestion is an adequate supply of gastric juice, and its thorough admixture with every particle of the food on which it is to operate. The *second* is a steady temperature of about 98° or 100° Fahr. The *third* is the gentle and continued agitation of the alimentary mass in the stomach during the digestive process. — Much light has been thrown upon the function of digestion, and consequently upon disorders of this function, by the experiments of Dr. BEAUMONT, of America, on ST. MARTIN, a strong young Canadian, who was wounded in the left side, a fistulous opening into the stomach remaining without detriment to the general health. For some months after the wound, the food could be retained only by wearing a compress and bandage; but early in winter, a small fold or doubling of the villous coat began to appear, which gradually increased till it filled the aperture and acted as a *valve*, so as completely to prevent any efflux from within, but to admit of being easily pushed back by the finger from without.

Dr. BEAUMONT describes the aperture in ST. MARTIN's stomach as being situated about three inches to the left of the cardia, near the left or superior termination of the great curvature. When the stomach was nearly empty, he was able to examine its cavity, to the depth of five or six inches by artificial distention. When it was entirely empty, the stomach was always contracted on itself, and the valve generally forced through the orifice, together with a portion of the mucous membrane, equal in bulk to a hen's egg. After sleeping for a few hours on the left side, the protruded portion became so much larger, as to spread over the neigbouring integuments five or six inches in circumference, fairly exhibiting the natural rugæ, villous membrane, and mucous coat, lining the gastric cavity. This appearance was almost invariably exhibited in the morning before rising in bed.

The first point which Dr. BEAUMONT conclusively settled is, that the gastric juice does not continue to be secreted between the intervals of digestion, and does not accumulate, to be ready for acting upon the next meal. The next which he established is that in health, the gastric secretion always bears a direct relation to the quantity of aliment naturally required by the system; so that if more than this be taken, there will be too small a supply of the juice for the digestion of the whole. Dr. BEAUMONT further ascertained that the gastric secretion, and the villous coat, undergo great changes during disease. In the course of his attendance on ST. MARTIN, he had opportunities of *seeing* what was actually going on in the organ, and of observing, that whenever a feverish state was induced by obstructed perspiration, or by stimulating liquors, or by overloading the stomach; and that when influenced by fear, anger, or other emotions, depressing or disturbing the nervous system, the villous coat became sometimes red and dry, and at others, pale and moist, having lost its smooth and healthy appearance. As a necessary consequence, the secretions became vitiated, impaired, or suppressed; and the follicles, secreting the mucus which protects the surface of the villous coat, became flaccid, and no longer yielded this bland secretion. The nervous and vascular papillæ thus deprived of their defensive shield were then subjected to undue irritation. When these diseased appearances were considerable, the system sympathised, and dryness of the mouth, thirst, quickened pulse, &c., showed themselves; and no gastric juice could be procured or extracted, even on the application of the usual stimulus of food. The dry, irritated appearance of the villous coat, and the absence of the healthy gastric secretion in the febrile state, as Dr. COMBE has remarked, not only explain at once the want of appetite, nausea, and uneasiness generally felt in the region of the stomach; but also show the folly of attempting to sustain strength, by forcing the patient to eat, when the food cannot be digested, and when nature instinctively refuses to receive it.

The inferences, drawn from the experiments and observations of Dr. BEAUMONT and others, that more immediately concern the subject under consideration, may be stated as follows: —

1. That the processes of *mastication, insalivation* and *deglutition* are important, not merely as subjecting the food to the gastric juice in a state of due preparation for its action, but also as allowing time for the regular contraction of the stomach upon each individual morsel conveyed into it, as well as transmitting the food in small portions at a time, so as to prevent a too rapid or excessive, and injurious distention of the organ. —

2. That the gastric juice is the agent of chymifaction; that it is secreted from vessels distinct from the mucous follicles; that it is a clear transparent fluid, without odour, a little salt, and perceptibly acid; and that it contains free hydrochloric acid, a little acetic acid, and some other active chemical principles. —

3. That this juice is never found free in the stomach, but is always excited to discharge itself by food or other irritants; that it is seldom obtained pure, but generally mixed with mucus, and sometimes with saliva; and that, when pure, it is capable of being kept for months, or even years. —

4. That it is a solvent of food, and alters its properties; that it checks the progress of putrefaction, corrects putrid substances, coagulates albumen and milk, and afterwards dissolves the coagula; and that it commences its action on food as soon as it comes in contact with it. —

5. That it is capable of combining with a certain fixed *quantity* of food; and when more is presented for its action than it will dissolve, indigestion will ensue; and that its action is facilitated by the warmth and motions of the stomach, these motions taking place chiefly in two directions, transversely and longitudinally. —

6. That the gastric juice is modified in quantity, and probably in its intimate constitution, so as to suit the kind of food; and hence the occurrence of indigestion on sudden alterations of the kinds, quality, and quantity of food.

7. That the action of the stomach and of its fluids is the same on all kinds of diet: and that the motions of the stomach produce a constant admixture of food and gastric juice, and thereby facilitate digestion. —

8. That *solid* food, of a certain texture, is easier of digestion than *fluid*; that *animal* and *farinaceous* aliments are more digestable than *vegetable*; but that susceptibility of digestion does not depend altogether upon natural or chemical distinctions. —

9. That digestion is facilitated by *minuteness of division* and *tenderness of fibre*, and retarded by opposite qualities. —

10. That the ultimate principles of aliment are always the same, from whatever food they may be obtained. —

11. That chyme is homogeneous, but variable in its colour and consistence; and that, towards the latter stages of chymification, it becomes more acid and stimulating, and passes more rapidly from the stomach. —

12. That soups and other liquid food do not call into play the muscular coat of the stomach; and before the gastric juice can act upon them, the fluid part must be absorbed and the mass thickened to a proper consistence for undergoing the usual churning motion; and, consequently that this kind of food often gives rise to acidity, particularly in weak states of the stomach. —

13. That, owing to the adaptation of the gastric juice to the nature of the food, sudden or extreme changes from one kind of diet to another is injurious; for the stomach has not had time to modify its secretions sufficiently to meet the altered demand upon its powers. —

14. That water, ardent spirits, and most other fluids, are not affected by the gastric juice, but pass from the stomach soon after they have been received; that heating condiments are injurious to the healthy stomach; and that the use of spirits always causes disease of this organ, if persevered in. —

15. That bulk, as well as nutriment, is necessary to articles of diet; and that digestibility does not depend upon the quantity of nutrient principles that aliments contain. —

16. That the quantity of food generally taken is more than the wants of the system require; and that such excess, if persevered in, generally produces functional disorder, and consecutively, organic disease. —

17. That oily food is difficult of digestion, though it contains a large proportion of nutrient principles.

18. That *bile* is not usually found in the stomach, and is not necessary for the digestion of food; but that, when oily food is used, it assists digestion. —

19. That gentle exercise facilitates digestion; and that the *acetic, citric*, and *hydrochloric* acids promote this process, particularly if vegetables and indigestible substances have been taken. —

20. That the time required for the stomachic digestion

the liver, of the intestines, of the heart, of the kidneys, or of any other organ; or they may be part only of some more general malady. Dyspepsia may thus be *idiopathic* or *symptomatic*. As presented to the physician in practice, indigestion is generally owing to the above conditions, in connection with the following: — 1. Deficiency, as to quality and quantity, of the fluids derived from the liver, pancreas, and intestinal mucous membrane. 2. Disorder of the circulation and functions of this membrane; and 3. Disorder of the consecutive and harmonious actions of the muscular coat of the small and large intestines.

38. IV. Treatment. — There are few diseases which require greater attention to its causes, and to its various states during the treatment, than this. The *objects* of the practitioner are: — 1. To ascertain the predisposing and exciting causes; 2. To draw a rational inference as to the pathological states on which the complaint depends; and 3. To examine into its associations, and to attend to the nature and relation of its complications, whether primary or consecutive. Guided by these *general intentions*, the more *special indications* are: — 1. To avoid the causes; 2. To give immediate relief to the more urgent symptoms, as acidity, cardialgia, flatulence, pain, costiveness, &c.; 3. To remove the pathological states and their consequences; and 4. To prevent a return of the disorder. These indications require to be fulfilled by means appropriate to the particular form of the complaint.

39. i. *Treatment of the Asthenic Form of Dyspepsia. A. In the more acute states*, it is sometimes necessary to remove the load by which the stomach is oppressed, or the substance by which it is irritated, by an *emetic*. But, unless when it is obvious that the disorder depends upon this cause, emetics are injurious, particularly a repetition of them. In such circumstances, the effect is soon produced by irritating the fauces by a feather, or with the finger; by a warm infusion of chamomile flowers; by tepid water, with common salt, or with an aperient salt, and by ipecacuanha. When pallor of the countenance, nausea, oppression, and the sense of a load at the epigastrium, and rancid or bitter eructations are present, emetics are indicated; and these are the most suitable means. But after the organ is evacuated, its functions should be restored by repose, and by small quantities of seltzer water, of iced water, or a cooling aromatic water, as spearmint, &c. Food should not be given till the appetite returns, when the lighter and more palatable articles may be taken. The bowels afterwards require to be evacuated, either by stomachic aperients, as rhubarb, with magnesia or soda, in an aromatic water, or aloes with an alkali, as in the compound decoction, or by enemata. Most of the means recommended in the article Constipation (§ 15. *et seq.*), and in several of the Formulæ of the *Appendix*, will likewise be appropriate in these circumstances.

40. When *nausea* continues after the stomach and bowels have been evacuated, or when the *vomiting* is protracted after offending matters are removed, medicines to relieve these symptoms should be prescribed, especially the *hydrocyanic acid*, in camphor julep, with a little compound spirit of lavender, or tincture of cardamoms, or a drop or two of *kreosote*, in the form of a pill, with powdered liquorice root. Effervescing draughts, with citric acid and ammonia, this last being somewhat in excess; or the liquor ammoniæ acetatis, with camphor mixture, or with spearmint water; or calcined magnesia, in this or in any other aromatic water, will also be serviceable. If these fail of affording relief, active purgative enemata will generally be efficacious, the symptoms disappearing as soon as a free action of the bowels is procured.

41. *Heartburn* is best treated by medicines, which act upon the secretions, and move the bowels. Rhubarb, with magnesia, and sesqui-carbonate of ammonia, in an aromatic water; blue pill, with castile soap; and alkaline solutions in bitter tonic infusions, or in lime water, are commonly employed, and are most useful when this symptom is connected with acidity. But when heartburn is attended by rancid, septic, or insipid eructations, the mineral acids, as the nitric, the hydrochloric, and the aromatic sulphuric acids, given in simple camphor, or aromatic water, or in suitable tonic infusions, will be most serviceable. Dr. Pemberton advises lemon-juice in these cases, and Dr. Todd, the phosphoric acid. When there is a liability to heartburn, wine, spirits, and particularly malt liquors, should be avoided. Hock or old sherry may, however, be taken in great moderation, in seltzer water.

42. *Pain*, or the slighter states of morbid sensibility, will be best removed by the *trisnitrate of bismuth*, conjoined with extract of *hop*, or extract of *hyoscyamus*; by *hydrocyanic acid* or *kreosote*, as directed above (§. 40.); by other anodynes, given with aromatics and antispasmodics; by the compound or fœtid spirit of ammonia, in suitable vehicles; by the compound galbanum pill, or the compound rhubarb pill, with henbane and ipecacuanha; by draughts of warm water, either alone, or with an alkali, or with magnesia. If pain be severe, and if *vomiting* have come on spontaneously, and continued after morbid matters are removed, a full dose of *opium*, with an aromatic, or of the acetate or hydrochlorate of morphia, similarly combined, should be prescribed. But the propriety and frequency of repeating it will depend upon the circumstances of the case. If *fla-*

---

depends upon the quantity and kind of food, and upon the state of the stomach; that the time required for the disposal of a moderate meal, in a healthy state of the organ, varies from three hours to three hours and a half or four hours; and that in states of indigestion, the process is delayed much longer than this, particularly as respects the more indigestible substances. —

21. That a diminution of the temperature of the stomach below 98° impedes digestion: and that the temperature of the organ is not necessarily elevated by the process. —

22. That whatever promotes organic nervous power, without exhausting it, favours digestion, as breathing a dry pure air, hilarity of mind, moderate laughter, &c. —

23. That the organic or ganglial nervous influence is more concerned in the process of digestion, than the influence conveyed to the stomach by the eighth pair of nerves; and that the circulating, absorbing, and especially the secreting functions of the organ are under the dominion of the former, whilst the sensibility and muscular contractions are directed by the latter. —

24. That the inference drawn by Dr. W. Philip from his experiments, as to digestion depending upon the influence of the eighth pair of nerves, and as to galvanism being capable of supplying the place of this influence, are unphilosophical, as they are formed without due consideration of all the circumstances, and as they leave out of the account the shock given to the system by the violent operations performed in these experiments.

tulence is troublesome, the means already advised may be prescribed, or those recommended in that article (§ 15.) may be employed. Friction over the epigastrium, especially with a stimulating liniment, will also give immediate relief from both pain and flatulence. When *headach* is present, the treatment proposed for *Dyspeptic* Headach (§ 46.) should be directed. For the *costiveness* so generally attendant upon this form of indigestion, the medicines already noticed, or those about to be prescribed, or a combination of mild aperients with tonics, deobstruents and alteratives being given occasionally at night, will prove of great service.

43. After an acute attack of dyspepsia, particularly when occasioned by errors of diet, it is necessary to enjoin abstinence, and thus afford the stomach time for repose, until its organic sensibility and functions begin to return. After a while, a cup-full of mutton or veal broth, or of green tea, or of coffee without milk, may be given and repeated; or a wine-glass full of port-wine negus may, in some cases, be allowed. But care should be taken in returning to a full diet; and the injunctions as to diet about to be stated ought to receive attention. In general, tonics and stomachics should not be prescribed until the functions of the stomach are returning.

44. *B.* Having removed the more acute attack of asthenic dyspepsia, with its urgent symptoms, the remaining disorder is in all respects the same as the more *slight and chronic states of the complaint*, and requires a similar treatment to them. The *third intention* of cure (§ 38.) should now be carried into effect; and the organic nervous energy, the secretions, and the muscular tone of the stomach be improved. This intention is to be effected chiefly by the *diet* and *regimen* hereafter to be noticed; but a judicious recourse to medicine will also prove of great benefit. The infusion of cinchona, of columba, of gentian, chamomile, cusparia, cascarilla, will be severally useful, with the alkaline carbonates, and small doses of stomachic tinctures. Afterwards the metallic tonics, as the tincture of the sesquichloride of iron, the sulphate of iron, the sulphate of zinc, the trisnitrate of bismuth, and the mineral acids, will generally be of service. Several of these may be given with the extract or tincture of hop, or of hyoscyamus. Lime water may be taken with aromatics, particularly when the bowels are much relaxed; and the aërated, or alkaline chalybeate waters may be used. When there is no complication contra-indicating cold bathing or the shower bath, it will be advantageous to resort to them frequently; and when uneasiness at the epigastrium is often felt, a warm plaster will be worn in this situation with benefit.

45. The most active or varied means employed to restore the functions of the stomach will be frequently inefficacious, if the offices of the collatitious viscera be imperfectly performed. The *biliary secretion* should therefore be promoted or corrected by occasional doses of blue pill, or Plummer's pill with soap: and the bowels preserved moderately open by mild purgatives, or by a combination of them with bitters and tonics. With this view, rhubarb may be conjoined with aloes, guaiacum, and ipecacuanha, or with magnesia; the infusion of senna, with the infusion of gentian; the compound decoction of aloes, with the decoction or extract of taraxacum; the sulphate of potash with rhubarb; the purified extract of aloes with castile soap, &c. — These and other mild purgatives may be taken in other combinations, as draughts, mixtures, or pills, as prescribed in numerous and various forms in the *Appendix*, and in the article Constipation. A judicious combination of bitters with mild purgatives, as, of sulphate of quinine, or inspissated oxgall with aloes (F. 562. 575.); the infusion of senna with any of the bitter infusions (F. 266.); and the decoction of aloes, with soda and infusion of columba, will generally be extremely useful in this state of the complaint.

46. When chronic asthenic dyspepsia is attended, not only by a torpid state of the liver, but also by incipient cachexia, or has given rise to cutaneous eruptions, &c., much benefit will result from the simple preparations of sarza, with liquor potassæ or Brandish's alkaline solution, and extract of taraxacum. If it have occasioned difficult or impaired menstruation, or a state of incipient chlorosis, as often observed in females in London, the preparations of iron, particularly the mistura ferri composita, the decoction of aloes being taken so as to act freely on the bowels; or the pilula ferri composita, conjoined either with the pil. aloes cum myrrha, or the pil. aloes composita; will generally remove all disorder, if sufficiently persisted in, and aided by change of air, diet, and exercise.

47. In this form of dyspepsia, the restoration of the digestive functions much depends upon a healthy state of the other excreting organs, as well as of the bowels. The functions of the kidneys and of the skin should be duly promoted and corrected. The temperature of the general surface, and the exhalations from it, ought to be preserved, and the urine duly examined, in order to ascertain, not only its appearance, but the general character of its chemical constituents. As these vary, or, as certain of them predominate, so should some of the most efficacious medicines, prescribed in the complaint, be varied or altogether changed; so should tonics be conjoined with alkalies or acids; and aperients and alteratives be given with absorbents or deobstruents.

48. ii. *The irritative variety of dyspepsia* requires very different means of cure from those just advised; but the removal of the exciting causes is as necessary in the treatment of it as in that of the foregoing. — *a.* In the more *acute states* of this variety, when pain, tenderness, heat, or soreness is felt in the epigastrium, although the vascular disorder of the villous surface may not amount, it nearly approaches to inflammation; and erethism, or vascular congestion, at least, exists. The application of *leeches* to the epigastrium then becomes necessary. In plethoric persons, a *bleeding* from the arm should be preferred. In those who have suffered from hœmorrhoids, or obstructions of the liver, *cupping* on the hypochondria, and in females, whose catamenia are deficient, leeches to the groins may be prescribed. Afterwards a large rubefacient plaster, formed either of equal parts of the compound pitch and ammoniacal plasters, or of seven parts of the former with one of the cantharides plaster, should be applied over the epigastrium. The blue pill, or hydrarg. cum cretâ should be taken at bed-time, and a mild aperient in the morning. Fresh castor oil,

assisted by cathartic enemata, will be useful in this variety. In some of the more acute cases, a full dose of calomel, either alone, or with a little James's powder, will be of service. Although calomel, when frequently exhibited, weakens the nervous energy, yet an occasional dose diminishes vascular action in the villous coat of the stomach, and excites the actions of the lower bowels. It should be followed by mild purgatives and active enemata; for by increasing the organic actions of the lower portion, the morbid states of the upper parts of the digestive tube, will the more readily subside. When this variety of dyspepsia is attended by an erythematic *redness*, or *soreness of the fauces and pharynx*, as it frequently is, sometimes extending down along the œsophagus, calomel, taken in the form of powder, aided by mild aperients and active enemata, will be of essential service, not only in acting in the manner just stated, but also in promoting the secretions of the liver and intestinal canal.

49. The other *urgent symptoms*, noticed with reference to the former variety, are generally much more severe in this, and require a somewhat modified treatment. But irritation, erethism, congestion, or even inflammatory action of the villous coat, are not the only pathological states characterising cases of this kind. Organic nervous power, the secretion of the gastric juices, and the tone of the coats of the stomach, are more or less weakened or disordered, and require to be strengthened, as well as corrected. At first, cooling medicines and diaphoretics are required, in order to remove irritation or vascular excitement; but they should afterwards be conjoined with mild tonics or gentle restoratives, and aided by a light farinaceous diet (§ 72.). If *nausea* or *vomiting* occur in this variety, the means already prescribed (§ 40, 41.) will generally remove them.— If they proceed from irritating ingesta, the gentle measures noticed above (§ 39.) will procure their expulsion. Afterwards small doses of the nitrate of potash, and of the solution of the acetate of ammonia, may be taken in camphor water.— When this variety is caused by intemperance, these medicines, aided by abstinence, will prove particularly serviceable. If pain or internal heat is complained of, or if vomiting continues after offending matters are removed, or after vascular depletion has been practised, the warm turpentine epithem, or a mustard poultice, may be applied over the region of the stomach, or one of the liniments above referred to, may be used as an embrocation in the same situation. The anodynes advised for the asthenic variety may also be taken, and cathartic enemata administered, until the bowels are freely evacuated. The medicines already recommended for *heartburn*, and for other unpleasant symptoms, will also be appropriate, after having had recourse to the means just advised.

50. *b.* In the *chronic states* of irritative dyspepsia, local depletions are requisite, only when there is evidence of plethora, or of increased action, or when natural secretions or accustomed evacuations are suppressed. Small doses of mild mercurials at bedtime, the simple preparations of sarza, either alone or with liquor potassæ, and external derivatives, are here extremely beneficial. After the secretions have been improved by these, and the excreting functions restored, the milder tonics conjoined with refrigerants and diaphoretics or anodynes, will be of great service. The decoction of Iceland moss and various other demulcents may be taken with hydrocyanic acid; and a plaster, consisting of either the ammoniacal, the compound pitch, or the compound galbanum plaster, may be worn on the epigastrium. I have generally preferred a plaster, consisting of equal parts of the compound pitch, and of the ammoniaco-mercurial plasters, and prescribed the following: —

No. 262. ℞ Potassæ Nitratis ʒ ss.; Liquor. Ammoniæ Acetatis ℥ i.; Infusi vel Decocti Cinchonæ ℥ iii.; M. Capiat Coch. ii. vel. iii. larga bis terve in die.

No. 263. ℞ Potassæ Nitratis ℈ i.; Liquoris Ammoniæ Acetatis ℥ i.; Aquæ Flor. et Infusi. Aurantii Comp. āā ℥ iiss.; Misce. Capiat tertiam partem, ter in die.

No. 264. ℞ Acidi Hydrocyanici, M. ii. Mist. Amygdalæ Dulcis; Aquæ Flor. Aurantii, et Mistur. Camphor. āā ℥ ss.; M. Fiat Haustus ter in die sumendus.

No. 265. ℞ Infusi Lupuli, ℥ ivss.; Acidi Hydrocyanici, M. viii.; Tinct. Aurantii et Tinct. Gentianæ comp., āā ʒ ii.; M. Capiat quartam partem bis terve in die.

No. 266. ℞ Liquoris Potassæ, ʒ iss.; Decocti Sarzæ. ℥ vii.; Extracti Sarzæ, ʒ iss.; Tinctur. Hyoscyami, ʒ i.; Tinct. Aurantii, ʒ iii.; Syrup. Sarzæ, ʒ ii.; M. Fiat Mistura, cujus capiat partem quartam ter quaterve in die.

No. 267. ℞ Infusi Valerianæ, ʒ x.; Acidi Hydrocyanici, ♏ ii.; Sodæ Carbonatis, gr. x.; Tinct. Cardamom. comp., ʒ i.; Spirit. Lavand. comp., ʒ ss; M. Fiat Haustus ter in die sumendus.

51. iii. *Treatment of the earlier consequences of dyspepsia.*—The treatment of several of these is fully discussed in the articles DUODENUM, FLATULENCE, HEADACH, HYPOCHONDRIASIS, PYROSIS, and STOMACH—*Painful Affections of*. It will therefore be unnecessary to advance much under this head.— *a.* When dyspepsia, in either of its forms, causes frequent attacks of relaxation and soreness of the throat and fauces, or inflammatory redness of these parts with cough, the diet of the patient should be strictly regulated, and mild purgatives, aided by cathartic enemata, prescribed. These attacks should not be neglected in persons presenting any tendency to bronchitis, or to pectoral disease. Some of the severest states of laryngitis and tracheitis have originated in irritative dyspepsia, the symptomatic irritation of the pharynx and fauces extending to the larynx, and exposure to cold, to currents of air, or to other causes, heightening the affection of the respiratory passages. A predisposition to affections of the respiratory organs, or tubercles in a latent state, are then often called into activity by neglected dyspepsia, owing either to symptomatic irritation or to consequent debility. In females, excessive menstruation, as to either the frequency or quantity of the discharge, is often the more immediate consequence, or intervenes between the dyspeptic disorder and the pulmonary affection. In such cases, the treatment should be directed both to the original disorder, and to the consequent affections; and fortunately, much of the means, both medicinal and dietetical, is appropriate to both; the more astringent and refrigerant tonics, and mild or cooling aperients, benefiting the disorder of the stomach as well as the superinduced complaints. To these medicines, ipecacuanha, camphor, and narcotics, will be added with advantage.

52. *b.* The *symptomatic disorder of the heart*, consequent upon one or other of the varieties of dyspepsia, requires chiefly attention to the original complaint. When palpitation is frequent, or the pulse intermittent, after the bowels have been

freely evacuated, and the secretions improved, camphor and ipecacuanha with hyoscyamus, — the sulphate of iron with extract of hop,—the decoction of senega with orange-flower water, or infusion of orange peel, and hydrocyanic acid, — the infusion of valerian similarly combined,— the nitrate of silver triturated with the extract of henbane, or of hop, will severally afford relief. In the irritative states of dyspepsia, particularly if signs of congestion, erethism, or inflammatory irritation, of the villous coat be present, the treatment advised above for this state ought to be premised. At the same time, some one of the warm plasters already prescribed may be applied to the epigastrium. In 1820 I first employed the *nitrate of silver*, combined with narcotics, for a case of dyspeptic palpitation, commencing with half a grain thrice daily, and increasing the dose to one grain. This patient, and others similarly affected, for whom I have ordered this medicine, perfectly recovered. Dr. J. Johnson has strongly recommended the nitrate of silver in dyspepsia; and certainly few medicines are more deserving adoption, when the patient is not alarmed at its use. It should, however, be very cautiously employed. This writer also insists much upon the use of the *sulphate of quinine* in most dyspeptic cases. In small doses, with sulphuric acid, in infusion of roses, it is an excellent medicine at that stage of the treatment when active tonics should be prescribed, especially when much debility is complained of. In order to prevent its constipating effects, it may be given with small doses of the purified extract of aloes, or with the aloes and myrrh pill; and when palpitations and other nervous symptoms exist, camphor and hyoscyamus will be added to them with great benefit. In females who have long laboured under dyspepsia, the quinine taken in solution is very serviceable when the catamenia are too abundant; but in other circumstances, particularly when a *chlorotic* state of the system, and impaired or obstructed menstruation have supervened, the *sulphate of iron* with the aloetic preparations should be preferred.

53. *c.* Of all the consequences of protracted and irritative dyspepsia, *disorder of the biliary functions and disease of the liver*, are the most common. When evidence of congestion, or fulness, or tenderness in the region of the liver exists, then the treatment should be commenced with general or local depletions—with cupping on the hypochondrium, or near the right shoulder-blade, or with the application of a number of leeches near the epigastrium, or around the anus. Small doses of blue pill, or of calomel, ought to be taken occasionally at bedtime, and to be followed by saline aperients in the morning. Alterative medicines consisting chiefly of the alkaline carbonates, or of the liquor potassæ, should be given daily, with taraxacum, sarzæ, and such of the other remedies above recommended, as may be appropriate to the case; but the treatment of this complication is fully discussed in the articles Gall-bladder and Ducts, Jaundice and Liver.

54. *d. Cutaneous eruptions*, both acute and chronic, frequently are associated with the more protracted states of dyspepsia, and are often consequences of these states. Yet they are seldom referred to these sources, or to these conditions of the villous surface of the stomach, of the digestive mucous surface generally, and of the biliary and other excreting functions with which they are so intimately connected. In numerous instances, heating, stimulating, and irritating medicines are prescribed, either prematurely, or at a time or stage of the treatment of these eruptions, when local or general depletions, refrigerants, evacuants, alteratives, and a low cooling diet, ought to have been employed. This remark is applicable also to those early indications of biliary disorder, of affections of the kidneys and urinary bladder, and especially of gout, which so often appear in the course of chronic indigestion.

55. Of the Diet and Regimen in Dyspepsia. Unless the *diet* of the dyspeptic be duly regulated, medical means will be employed in vain. On the subject of diet with reference to indigestion, Dr. Paris, Dr. A. Combe, Dr. Robertson, Dr. Ticknor, Dr. T. J. Todd, and Mr. Mayo, have furnished much information of the best kind, and conveyed it in the most agreeable manner. It is impossible to adduce any thing on this topic which has not been already stated and illustrated by these able writers.—i. *In considering diet with reference to indigestion generally*, there are various circumstances requiring particular notice: 1st, The kinds and quality of the food; 2d, The quantity and congruity of the food; 3d, The times of eating, or the periods which should intervene between meals; 4th, The kind and quantity of drinks; and 5th, The conditions deserving notice in connection with eating and drinking.

56. *A. The kinds and quality of food.* — *a.* Dr. Combe justly remarks, that a direct relation ought always to subsist between the qualities of the food and the nature of the constitution which it is intended to support. The highly concentrated and stimulating food necessary for the support of those who take very active exercise will prove too exciting to the irritable constitution of persons possessed of great activity of the brain and nervous system; and the generous diet, which suffices to rouse or support a phlegmatic system, will prove too nutritive for a person of a florid and sanguine temperament. For persons of a florid complexion, with great activity of the circulation, and a consequent liability to inflammatory diseases, the food ought to be calculated to sooth rather than to stimulate. Red meat, spices, wines, and fermented liquors, ought to be used sparingly, and the principal support derived from soups, fish, mucilaginous vegetables, acidulous fruits, and diluting drinks. In lymphatic persons, on the other hand, where the circulation is weak and slow, and the functions feeble, benefit is derived from a larger proportion of animal food, while vegetables, soups, and fluids, prove relaxing. To these persons, wine in moderation and spices are useful, if much exercise be taken. Persons of a highly nervous temperament, of great excitability and sensibility to impressions, are injured by heating or stimulating diet. White meats, as fowl and fish, farinaceous and mucilaginous aliments, and ripe fruits, are most appropriate to them. Where the bilious temperament predominates, and much active exercise is taken in the open air, a full supply of animal food is necessary, and a moderate allowance of wine or other stimulus is borne with less detriment, if not with more advantage, than in the sanguine and nervous temperaments. Where the constitution is of a mixed nature, a diet composed of animal and

vegetable substances in nearly equal proportions is, under ordinary circumstances, the best. — The food, also, should be adapted to the age, state of health, and mode of life of the individual, and to the climate and season of the year. A diet which would be quite sufficient to a person of sedentary occupations, would be inadequate to support an individual subjected to frequent or constant exertion; and in warm climates and seasons, a smaller supply of food, particularly of a heating or stimulating kind, is necessary, than in cold and temperate countries. In the former but little animal food is requisite; in the latter, especially in very cold regions and in rigorous seasons, an abundant supply of this kind of diet becomes indispensable.

57. *b.* Although there are few articles of diet which a healthy person, leading a sufficiently active life, may not eat with impunity, there are many which ought to be preferred, and others which should be avoided, by the dyspeptic. *Vegetables* are slower of digestion than animal and farinaceous aliments, and more liable to undergo the acetous fermentation in weak stomachs, and to occasion acidity and flatulence. Fat and oily meats are also very indigestible, and give rise to acid or rancid eructations and heartburn. Soups and liquid food are acted upon by the stomach with great difficulty; and, if the diet consist chiefly of them, they furnish insufficient nourishment, and never fail of producing the more severe forms of dyspepsia, and the diseases of debility. Soups are hurtful when taken at the commencement of a full meal; but when little or no animal food is eaten along with them, and rice or bread is taken with them, so as to promote their consistency, they are digested with greater ease. Pastry, puddings, rich cakes, and articles containing fatty or oily matter, are the most indigestible of all kinds of food. Plain well-cooked animal food, particularly venison and game, kept a due time after it has been killed, and eaten in moderate quantity, with bread, or with roasted, mashed, or dry mealy potatoes, or with rice, is one of the most digestible meals that can be taken by the dyspeptic. The kind, however, of animal food, and the modes of dressing it, should depend much upon the state of disorder, and the age and constitution of the patient.

58. *c. Fish* holds an intermediate rank between the flesh of warm-blooded animals and vegetable food, as respects digestibility. It is less nutritious than mutton or beef; and a larger quantity is requisite to satisfy the appetite. Whiting, haddock, and skate, are the most digestible of salt-water, and perch of fresh-water fish. Gurnard, cod, soles, and turbot, are successively richer and heavier, but easier of digestion than mackerel, herrings, eels, or salmon. Eels are, however, more digestible when they are stewed. Salmon is very indigestible, as usually obtained from the London fishmongers, for the reasons stated in the article Disease (§ 46.); but it is not indigestible when quite fresh and properly cooked. The same observation applies to mackerel and herrings. Fish is most digestible when *boiled;* it is less so when *broiled;* and the least so when *fried.* The dyspeptic should eat it dressed only in the first of these ways. Shell-fish is slow of digestion; some much more than others. Raw oysters are more digestible than crabs or lobsters; but oysters, when stewed or otherwise cooked, are heavier than either. Fish is often rendered indigestible by the sauces, &c., taken with it. Vinegar, however, and lemon-juice promote the digestion of it. Malt liquor ought not to be drank with fish. Fruit should not be eaten with it; and milk, likewise, should be avoided.

59. *B.* The *quantity of food* should always be proportioned to the digestive powers of the stomach and the wants of the system. Where waste is great, and growth active, an abundant supply of food is requisite, and the desire for it is commensurate with the demand. Those who lead sedentary lives, and whose circumstances admit of free living, are peculiarly liable to dyspeptic complaints, owing chiefly to the quantity of food indulged in. It is indispensable to a due and natural supply of aliment to the stomach, that attention be paid to the preliminary processes of mastication and deglutition. If these be performed too hastily, too much food will be received in a short time, in a state of insufficient preparation, and the stomach will be overloaded, before the sensation of hunger can be completely allayed. As the dilatation of the stomach by the ingesta, should be gradual, and ought not to exceed a certain limit, and as a definite quantity of gastric juice is secreted, according to the wants of the system and the habits of the individual, if more than the usual quantity of food be taken, the organ will be over distended and a part of it will remain undissolved, producing the usual symptoms of indigestion. Such being the case even with the healthy, how much greater will be the disorder when excesses are committed by the dyspeptic. Sir F. Head very justly remarks, "that almost every malady to which the human frame is liable is, either by high-ways or by-ways, connected with the stomach; and I must own, I never see a fashionable physician mysteriously counting the pulse of a plethoric patient, or, with a silver spoon on his tongue, importantly looking down his red inflamed gullet, but I feel a desire to exclaim, 'Why not tell the poor gentleman at once — Sir, you 've eaten too much, you 've drunk too much, and you 've not taken exercise enough!'" — Dr. Abercrombie observes "when we consider the manner in which diet is generally conducted in regard to the quantity and variety of food and drink, instead of being astonished at the prevalence of indigestion, the wonder should be that any stomach, having such duties imposed on it, is capable of digesting at all." Much, certainly, is to be done in dyspepsia, by attention to the quality of the articles of food, but *much more depends upon the quantity.* Indeed the dyspeptic might almost be independent of attention to the former, if he rigidly observed the latter. This opinion is supported by the experiments of Dr. Beaumont, showing that the power of digestion is limited by the amount of gastric juice provided by the stomach — an amount varying with the modes of life and the wants of the system. It is superfluous to remark that second courses, served up to gratify the pride of the host, overcome the stomach, paralyse digestion, and occasion acute attacks of indigestion.

60. It is impossible to assign any rules respecting the quantity of food that should be taken, as it depends upon so many circumstances. Mixtures of different kinds of food are injurious to digestion,

chiefly by the inducement to excess in quantity, which the variety affords, and by the incongruity of many of the articles. When only one dish is partaken of, Dr. Combe remarks, there is less temptation to exceed the quantity, than when several are tried. The first intimations of a satisfied appetite, are warnings to stop eating, which should never be neglected by dyspeptics. If these be passed by, indigestion or an aggravation of it, where it is already present, will always result. The quantity of food should also have reference to the amount of exercise. When little or no waste is excited by exercise, the supply should be remarkably moderate, as well as digestible. Persons who have removed from the country, where they have enjoyed active exercise in the open air, and have consequently digested well a full diet, generally become dyspeptic when they have removed to large towns, and are subjected to very different circumstances, especially if they continue the same quantity of food, or if they increase it.

61. C. The *times of eating*. In general, five or six hours should elapse between one meal and another. Even in healthy persons, digestion of a full meal is seldom over in less than four hours; and in dyspeptics, it is seldom disposed of until a much longer period has passed. The stomach, also, requires an interval of rest after the process is finished, in order to enable it to enter upon the vigorous digestion of the next meal. If food be taken before the organ has recovered itself from its previous exertion, the secretion of the gastric juices, and the muscular contractions, will be imperfect. The whole of the gastric juice which the stomach can secrete in a given time being engaged in the digestion of the first meal, the one taken too closely upon it will be insufficiently acted upon, and thereby undergo fermentation. The intervals between meals should be in relation to the quantity eaten, and the habits of the individual as to air and exercise. When the latter are enjoyed, the periods may be much shorter than when the habits are sedentary.

62. For dyspeptics, as well as for healthy persons, the meals should be regulated according to the necessary occupations and habits of the individual. For those, observes Dr. Combe, who work by day and sleep by night, an early breakfast, an early dinner, and an early evening meal, will be most conducive to health. But for those who, against the laws of nature, keep late hours, late breakfasts and dinners are preferable. — Persons who eat suppers ought not to breakfast till one or two hours after rising; but those who dine late and eat nothing afterwards, require breakfast sooner. As a general rule, breakfast about half an hour or an hour after rising will be found most beneficial. Those who are obliged to rise very early, should take a cup of coffee or tea with a biscuit soon after getting up, and a more substantial breakfast about three hours afterwards. If exposure to cold, to the morning dews, or to unwholesome air, or to any other cause of infection be incurred in the morning, the stomach should be fortified by coffee or by breakfast. The dyspeptic, especially, ought never to travel, or to enter upon any exertion with an empty stomach, and never with an overloaded one.

63. As a general rule, not more than five or six hours should elapse from breakfast till dinner. For youth and convalescents, and for persons taking active exercise in the open air, the interval may be somewhat shortened; but for sedentary persons, it may be much prolonged. Much, however, should depend upon the appetite, which ought to have returned some time before dinner is taken. According to this, the most suitable time for this meal, is about two o'clock. As many dyspeptics as well as others cannot dine until much later in the day, ought nothing to be taken till five, six, or seven o'clock? or ought a light repast to be taken at one or two o'clock, and the appetite be chiefly reserved for a substantial meal at a much later hour? When dinner cannot be taken until eight or nine hours after breakfast, it will be necessary to have some refreshment in the meantime; but it should be in relation to the time that will elapse until dinner, and to the exercise taken. For persons of sedentary habits, a biscuit and a glass of water will be sufficient; but for the active and the young, especially if the interval be long, a more substantial luncheon is necessary. The habit of resorting to pastry-cooks for refreshment, and of taking wine with it, is generally prejudicial, and particularly in dyspepsia. When dinner cannot be taken until a late hour, it should always be postponed for half an hour or an hour, until excitement or fatigue has subsided.

64. When the dinner is early — from one to three o'clock — a light meal of tea or coffee and bread is necessary; but when the dinner is late, or little exercise is taken after it, tea or coffee should be used merely as a diluent, and no food ought to be eaten. After an early dinner, admitting of time for its digestion and a return of the appetite before a late hour, a third meal, of light aliments, and in moderate quantity, should be taken, particularly by persons engaged in the open air. When ultra-temperance is practised by the dyspeptic, particularly when he lives actively, and retires to bed with an entirely empty stomach, he is quite as likely to have disturbed sleep and unpleasant dreams, as if he had his stomach loaded. He may even be wakeful and irritable, or experience a sense of unpleasant emptiness or gnawing at the stomach. All these may be removed by a basin of arrow-root or sago, about an hour before bedtime. A light supper may therefore be taken, when the dinner is early; but it should be at least an hour or two before retiring to rest.

65. D. The dyspeptic, as well as other valetudinarians, inquire, *What ought we to drink?* but they rarely follow the question by the next important one, *When should we drink?* And they never inquire as to *the temperature at which fluid should be taken*. *a.* Respecting the *first* of these questions, it may be stated, that *water* — either spring water, or toast-water, is the safest if it be taken only according to the dictates of thirst. Whey, fresh small beer, soda water, and seltzer water, are of service in many cases, as will be noticed hereafter; but fermented liquors and wines require greater restrictions. The young dyspeptic ought never to drink any thing but water, toast-water, or whey. The more stimulating beverages will be prejudicial to him, unless during states of debility, for which it may be necessary to prescribe them medicinally. Of all these, spirituous liquors are the most injurious, and ought never to be taken in any form, nor in any variety of indigestion. Some of the asthenic states of the complaint, which are benefited by a moderate

use of wine, are exasperated by spirits, or even by malt liquors. Dr. BEAUMONT found on examining ST. MARTIN's stomach, after a free indulgence in ardent spirits for several days, the villous surface covered with erythematic and aphthous patches, the secretions vitiated, and the gastric juice diminished in quantity, viscid, and unhealthy, although he complained of nothing, not even of impaired appetite. Two days later, when matters were aggravated, the erythematic appearance was more extensive, the spots more livid, and from the surface of some of them, small drops of grumous blood exuded. The apthous patches were larger and more numerous, the mucous covering thicker than usual, and the gastric secretions much more vitiated. The fluids, extracted from the organ, were mixed with much thicker ropy mucus and muco-purulent discharges, slightly tinged with blood. Yet ST. MARTIN complained only of an uneasy sensation, and a tenderness at the pit of the stomach, with vertigo and dimness of vision on stooping. The tongue was covered with a yellowish brown coating, and the countenance was somewhat sallow. After a few days of low diet with mild diluents, the inner surface of the stomach assumed its healthy state, the gastric juice became clear and abundant, the secretions natural, and the appetite voracious. Dr. BEAUMONT adds, that the free use of ardent spirits, wine, beer, or any intoxicating liquor, when continued for some days, invariably produced these morbid states. Eating voraciously or to excess, and swallowing food imperfectly masticated, or too fast, produced the same effects when repeated frequently in close succession. (*Exper. and Observ. &c.* p. 237.). He often observed that, when stomachic disorder, with febrile symptoms, was present, or when influenced by violent mental emotions, the villous coat of the stomach became red, irritable, and dry; and that but little gastric juice was secreted on the food being taken, digestion being very much prolonged. No more wine, therefore, nor more of any other fermented liquor, should be taken, than may be found sufficient to support the strength and ameliorate the symptoms of the dyspeptic, without quickening the circulation.

66. *b.* As a general rule, the *desire for fluids* is the chief indication of *the time* at which they ought to be taken; but large draughts should be avoided, as the stomach becomes suddenly distended, the juices diluted, and the muscular coat weakened by them. Besides, much more fluid may be thus taken than is necessary for the wants of the system. The dyspeptic ought never to drink largely, either during, or soon after, a meal. Frequent sipping, or drinking by mouthfuls, will be much more beneficial, and ultimately, more quenching of thirst. Mild drinks are best taken about three or four hours after a solid meal. It is then that tea and coffee are used as beverages. These are always injurious when made too strong, or taken in large quantity, especially to the dyspeptic. Soda water drank at the time of dinner is hurtful, by distending and over exciting the stomach. Seltzer water is less so; but it is often of service some time after a meal, when there is much thirst. Soda water is then sometimes also of use.

67. *c.* The *temperature at which fluids should be taken* is of the utmost importance to the dyspeptic. *Extremes* of temperature are injurious even to the healthy, and not only to the stomach but also to the collatitious viscera, and to the teeth. The bad effects of the ingestion of large quantities of cold water into the stomach have been often demonstrated; but the subject has been very superficially considered. Dr. BEAUMONT remarked, that a gill of water, at the temperature of 55°, received into ST. MARTIN's stomach when empty, reduced the heat of the organ from 99° to 70°, at which it stood for a few minutes, and then rose very slowly. This experiment explains the injurious effects produced upon weak stomachs by cold fluids taken during digestion, and the fatal effects of very copious draughts of cold water whilst the body is fatigued and perspiring; the shock which the constitution receives from having the temperature of the most vital and central organ suddenly and remarkably depressed, paralysing the other vital movements. It having been demonstrated, that a temperature of 98° is requisite to healthy digestion, it must follow, that the use of ices, and particularly iced creams after dinner, or when digestion is proceeding, will be most injurious. A fit of indigestion is often caused by them; and they seldom fail of lowering the vital tone of the stomach during the digestive process. The moderate use, however, of cold or iced water, or of water ices, when this process is completed, and when there is no exhaustion, is beneficial, by inducing a salutary reaction in the organ. Ices can be only taken slowly, and in small quantities at a time; hence they produce a much less sudden fall of temperature of the stomach than draughts of cold fluids. Dr. DUNGLISON states, that labourers in Virginia were frequently killed by drinking copiously of spring water when over-heated; but that such accidents have rarely occurred since they have been supplied with ice. The proper temperature at which soups, tea, coffee, chocolate, &c., should be taken, may be stated at about 100°; and at this grade of heat, liquids will be found more quenching to thirst than at a higher or lower temperature.

68. *E.* The *conditions necessary to promote a healthy digestion* require a brief notice. The determination of the circulating fluids to the digestive mucous surface and collatitious viscera, and the copious secretion from these viscera during digestion, require that the function should not be disturbed by moral or physical perturbation or exertion. Rest of body and tranquillity of mind for a short time before and after, but particularly after eating, is hence conducive to digestion. Whatever derives the nervous energy and the circulating fluids from the digestive viscera, or causes oppression of these viscera by over-loading the large veins, is injurious during digestion. Hence blood-letting, hot or cold bathing, mental shocks, exertions of any kind, and other circumstances which operate in this way are more or less hurtful. As the quantity of gastric juice requisite to the digestion of a full meal is generally secreted in an hour or an hour and a half after it is taken, or at least within two hours even in the dyspeptic, bodily and mental repose is beneficial during this time. It is thus that a *siesta* after dinner is found so serviceable to the dyspeptic. But, by promoting digestion, it favours supply, diminishes waste, and consequently induces vascular plethora, and the usual consequences of

this state, particularly in respect of the brain and liver. In dyspepsia, the desire for rest after a repast is great in proportion to the quantity eaten, the nervous energy being concentrated in the digestive viscera, in order to dispose of the ingesta. The state of the mind has a powerful influence on digestion: hilarity and ease of mind promote this function; whilst care, anxiety, envy and dissatisfaction, impede it. Dr. CALDWELL remarks, that dyspepsia commences perhaps as often in the brain as in the stomach. It is almost exclusively a complaint of the studious, the scheming, the daring adventurer, the stock-jobber, and the speculator, and of those who, over-exerting their brains, thereby injure them.

69. ii. *Of the Diet and Regimen with reference to the different states of Dyspepsia.* The observations of Dr. TODD as to the diet suitable to the different states of dyspepsia, are extremely just and precise; I shall, therefore, avail myself of some of them. *A. During the asthenic forms of indigestion*, the quantity of food should be reduced to the power of disposing of it; such articles as are difficult of digestion and weaken the stomach being altogether withdrawn.—*a.* The patient should be confined to a spare diet of animal food, and to a restricted use of fluids. A bulky meal ought always to be avoided; and when the appetite is impaired, abstinence will be frequently preferable to the use of stomachics. When the appetite does not fail, which is often the case when dyspepsia is produced by mental exertion, the patient should cease eating before the appetite is altogether allayed. The tea or coffee at breakfast should be taken with very little milk and sugar, and very little butter ought to be used. An egg, lightly boiled, may be eaten by those who take sufficient exercise. The dinner should consist of lean animal food, particularly mutton, poultry, game, and venison, which ought to be roasted or broiled. Bulky vegetables should be avoided; but mealy potatoes, yams, or rice, mixed with the gravy of the meat, young summer turnips, cauliflower, or French beans, may be taken sparingly. The least hurtful fruits are strawberries, morel cherries, and mulberries; but they should be eaten as a part of the luncheon, rather than after dinner. Fluids, even when there is thirst, should be taken slowly, and in small quantity, and always after a meal. If the digestion or habit require the stimulus of wine, old sherry or old port, with an equal part of water, should be preferred; but the quantity of either or of both should not exceed two or three glasses. Twice-dressed meat, *rechauffées*, and made dishes, ought not to be eaten; and the food should be masticated slowly and thoroughly.

70. *b.* The *kinds of food* most injurious in this variety of dyspepsia, and therefore to be avoided, are sweet, mucilaginous, or acid fluids, and such as contain much milk; puddings, compound dishes, and meat pies; new bread, or heavy unfermented bread; compact or fat dumplings, and pultaceous articles; creams, curds, custards, cheese, and all preparations of milk; fat meat, particularly pork or bacon, young meat, all gelatinous parts of meat, and salted or smoked meat; the less digestible species of fish, and all shell-fish; strong broths, gelatinous soups, or concentrated dishes; melted butter, oil, sauces, spices, condiments, and pickles; bulky or flatulent vegetables, especially cabbages, waxy potatoes; pot-herbs, beans, peas, cucumbers, &c.; most fruits, whether fresh or preserved; currants, gooseberries, apples, plums, melons, all kinds of nuts or kernels, and preserves or jellies. Malt liquors, particularly ale, perry, cider, home-made wines, punch, and shrub should also be avoided.

71. *c. Regular exercise* ought to be taken in th open air; and the kinds of exercise that bring th greatest number of muscles into moderate action should be preferred. CELSUS very justly advises persons subject to stomach complaints, to exercise the upper extremities and parts of the body. There are several amusements which have this effect, especially billiards, fencing, rowing, cricket, &c. For females, singing, dancing, skipping, battledore, dumb-bells, and the exercises recommended by Mr. D. WALKER, will be found very serviceable, especially when confined to the house by weather, or when exercise on horseback or on foot cannot be taken.

72. *B.* The *diet and regimen most suited for the irritative states of indigestion* differ considerably from those now recommended. In this variety, bland, farinaceous, and semi-fluid food, in small or moderate quantity, is the most appropriate, until vascular disorder of the villous coat of the stomach is removed by treatment. Saccharine, farinaceous, feculent, mucilaginous, and acidulous articles of food are most easily digested in this condition of the organ. Gentle exercise, as gestation in a carriage or on horseback, sailing, swinging, and walking, is preferable to the more exciting kinds of exercise. After digestion is completed, tepid or warm bathing, and frictions of the surface, are generally beneficial. When vascular excitement is removed, the patient may gradually adopt the diet advised for the preceding variety, beginning with light chicken, mutton, or veal broth, with toast or rice; and afterwards the more digestible kinds of solid food may be used.

73. *C.* The *wines and beverages* best suited for indigestion are old sherry or port diluted with equal parts of water, the finer kinds of claret, hock, white hermitage, and Sauterne; but these should not be taken in the irritative forms of dyspepsia until vascular excitement of the villous coat of the stomach is removed. The diluents most beneficial are seltzer water with a small quantity of hock, or seltzer water with milk or whey, or lime-water with milk or black tea, according to the peculiarities of the case. In the more irritable states of the stomach, whey, goat's whey, small quantities of seltzer water, or the imperial drink, should be preferred. When the state of the urine indicates the impropriety of using vegetable or mineral acids, the alkaline carbonates may be substituted; but, when indigestion has induced a torpid or disordered state of the biliary organs, not connected with inflammation, beverages slightly acidulated with the nitro-hydrochloric acids will be found serviceable.

74. *D. Several mineral waters*, both natural and factitious, are most excellent aids in the treatment of the several forms of indigestion.—*a.* In the *asthenic variety*, the mineral springs of Clifton, Malvern, Bath, and Tunbridge Wells, and the carbonated chalybeate waters of Spa, Pyrmont, Carlsbad, Marienbad, Swelbach, and Eger, on the Continent; or their imitations prepared by Dr. STRUVE, are generally beneficial.—*b.* In the *irritative states* of dyspepsia, the springs of

Harrowgate, of Ems, Plombières, Vichy, and of Marienbad, or other alkaline mineral waters, will be used with advantage. When the functions of the liver are disordered, the waters of Cheltenham or Leamington, or of the Beulah Spa, and the springs of Seidschutz and Pullna may be preferred; but when excitement of the villous coat of the stomach, and when the functions of the excreting viscera are restored, the aerated chalybeate waters, already mentioned, will be most serviceable.

INDURATION. — Synon. *Induratio* (from *Indurare*) to become hard. *Induration*, *Endurcissement*, Fr. *Induramento*, Ital. *Die Härtung; verhärtung*, Germ. *Hardening*.

Classif. — General Pathology. — *Morbid structure — Therapeutics.*

1. Induration is either *physiological* or *pathological*. The former proceeds — *first*, from the changes which take place in the tissues during the progress of Age (see that article); and *secondly*, from the increased nutrition and vital cohesion, consequent upon great activity of the vital manifestations of the part. This latter state, however, can hardly be termed induration. The *general pathological relations of induration* only require notice at this place. The specific conditions of it in the different tissues and organs are noticed in the articles on the pathology of these parts.

2. i. Induration may exist in a *simple state*, and unconnected with any apparent deposition of fluid or morbid product. In this case, it is merely a greater density of the natural structure, owing to some change in its nutrition, without any morbid secretion or further lesion of organisation. Various tissues and organs occasionally present this alteration, as the brain, the liver, the muscular structure of the heart, the cellular and fibrous tissues, the bones, the glands, pancreas, ovaries, &c. It may be independent of any change in the size or form of the part; but it is often connected with an increase of size, constituting *hypertrophy with induration*.

3. ii. Induration may depend upon an *infiltration of a fluid or solid matter* into the areolar or peculiar structure of a part — of serum, lymph, albumen, fibrine, or even of blood. The excited, or otherwise altered, action of the capillaries of the part may give rise to the effusion of these matters in a more or less fluid state; but they subsequently undergo various changes as to consistence or even organisation, their watery parts being absorbed, and the albuminous or fibrinous portions becoming more or less changed, or even identified with the structures which they infiltrate. Many of the lesions observed in the cellular tissue and parenchymatous organs — in the lungs, liver, spleen, glands, &c. — are owing to this species of alteration.

4. When the matter thus deposited is of a *peculiar or adventitious nature*, whether pre-existing in the blood, or produced by a change in the vital condition of the part, or of the constitution, the tissues, which are the seat of induration, undergo a succession of changes, and they as well as the matter which infiltrates them, or is deposited in them, assume peculiar forms, as in scirrhus, cancer, &c.

5. iii. Induration may proceed from the *absorption of the more fluid constituents of the tissues*. This seldom occurs, excepting from compression, owing to the effusion of fluid, or the development of morbid structures in their vicinity, or in enveloping parts. Effusions in the pleura and false membranes formed on its surface produce this change in the lungs; and the fibrous or fibro-cartilaginous formations in other situations produce a similar alteration, as in the spleen, &c. This form of induration may often be said to be rather a state of condensation or atrophy with induration. The distension, produced by the accumulation of natural secretions cannot be comprised amongst the forms of induration.

6. iv. Indurated parts *vary in appearance* — in colour, size, and form. 1. The *colour* is generally

changed, being often pale, owing to diminished vascularity and the deposit of albuminous matter; and sometimes red, greyish brown, yellowish, &c. These hues evidently depend upon the vascularity, and the state of stagnant fluids, and of effused or infiltrated matters. 2. The *size* of indurated parts may not be changed; more frequently it is increased, and sometimes it is diminished. 3. The *form* of the indurated part may or may not be altered.

7. v. The *causes* of induration may, in general terms, be stated to be whatever excites the vital actions of the part, or occasions a slight or protracted irritation of its capillaries. Induration from compression, however, cannot be ascribed to these causes. M. ANDRAL remarks that,— 1. Irritation may be the first phenomenon apparent, evidently preceding irritation and continuing with it. — 2. Irritation, having produced induration, may cease, induration alone continuing. — 3. Induration sometimes occurs without any evidence of pre-existing irritation. — 4. At an advanced period of induration, the quantity of blood sent to the part is actually less than before its induration, its vitality being also less than before this change of structure. — 5. In some cases, a secondary irritation may arise, at a longer or shorter period after the formation of induration. This secondary irritation sometimes restores the indurated part to its healthy condition; but more frequently it is productive of the most injurious consequences, causing ulceration, softening, &c.

8. vi. TREATMENT. —Induration in vital organs can seldom be ascertained, so as to enable the physician to enter upon its treatment with much hope of success. Alterations of sensation, motion, and size, sometimes lead to a belief in its existence. When these exist with weight or tension, and marked disturbance of function, vascular depletion, general or local, according to circumstances, derivatives and courses of alteratives, are the chief means upon which reliance can be placed. The alkaline solutions, the preparations of iodine, and mild mercurials, with narcotics, are sometimes useful; and the various modes of deriving irritation to external parts, should not be neglected. But both alteratives, deobstruents, and derivatives, ought to be continued for a sufficient time to test their efficacy. When the indurated part is near the surface, deobstruent plasters, and frictions with discutient liniments, embrocations and fomentations, may be severally employed. In all cases, it is necessary to prevent disorder of the digestive organs, to allay pain and irritation by anodynes, to promote the natural secretions and excretions, and to preserve the constitutional powers by light nourishment and change of air. When induration proceeds from compression, the removal of the compressing cause should be attempted, if circumstances admit of its accomplishment.

INFECTION. — SYN. From *Inficio*. *Contagium*, *Conterges*, *Contagio* from *con* and *tango*, Lat.; *Infection*, *Contagion*, Fr.; *Ansteckung*, Germ.; *Infezione*, *Contagione*, Ital. *Contagion*.

CLASSIF. — GENERAL PATHOLOGY — *Etiology*. GENERAL THERAPEUTICS — *Prophylactics*.

1. In the view which I am about to take of infectious agents, of their operation, and of their effects, it will be necessary to premise a few remarks as to the meaning I would attach to the word *infection*, as well as to other terms which have been usually considered as synonymous with it, or as expressing modes of the same agency. By some writers, the words *infection* and *contagion* have been received as altogether synonymous, whilst others have drawn distinctions between them. Few, however, of the latter have agreed on the subject. QUESNAY first attempted to give precision to the application of these terms, but with little success. Since his time the word *infection* has been commonly applied to the communication of disease from the sick to the healthy, by a morbid miasm or exhalation diffused in the air; and the word *contagion* to the transmission of a specific malady by immediate or mediate contact. But it is obvious that these are merely modes of the same agency in the majority of instances; for the humidity of the air becomes a medium of contact in the former, as much as the clothes of the sick are the media of it in the latter, the chief difference being, that the one acts only by being diffused in the air, whilst the other may act either in the same way, or it may directly convey a consistent virus or morbid secretion. In cases where substances have become the media of absorbing and retaining the morbid emanations or the effluvia of specific diseases, and thereby transmitting them, it must not be inferred that the infection is produced by contact of any part of the external surface of the healthy person with the substance thus imbued. The clothes worn by a person whilst labouring under a disease strictly contagious, even according to the above acceptation, may be so imbued with the morbid exhalation as to retain it for a long time, especially if shut up from the air, and may afterwards emit it upon being unfolded and exposed, and thereby propagate the disease to an individual who has never come in contact with the substance which has thus proved the *fomes* of contagion. Instead, therefore, of considering these distinctions as constituting a true difference, it will be preferable to view *contagion* as a *mode* of infection, to which certain limitations should be attached.

2. M. ROCHOUX considers that infectious agents may be divided into those which, like germs, are capable of reproducing and multiplying themselves as organised bodies, and into those which are devoid of this character, and require for their propagation certain accessories, without which they will not appear. The former of these represent contagions, the latter infections. M. DUPUYTREN observes, that *infection* is the contamination of the air by persons confined in low, close, ill-ventilated, and dirty situations, and by vegetable and animal substances undergoing decomposition, the emanations with which the air is thereby charged acting on man as poisonous agents. The sources of these emanations are

active in proportion to the grade of atmospheric humidity and temperature, and to the nature and quantity of the miasms which the air contains. *Contagion*, on the other hand, he considers to be in many respects independent of atmospherical conditions, and a species of germ or virus developed in the bodies of the sick, or forming an atmosphere around them containing the principle of the malady; and through the medium of this germ, virus, or morbid principle, the malady is transmitted to the healthy. When we consider the diverse states and kinds of agents to which the terms infection and contagion have in general been indiscriminately applied, and the close approximation of several of these agents to each other, as respects their properties and effects on the living economy; and when we further consider the modifications each of them experiences in the ever-varying conditions in which they present themselves, and from the several circumstances and accessory influences which are associated with them, the difficulty of assigning to them specific distinctions will be evident. Yet the difficulty should not preclude attempts at distinctions, and at arrangements founded on such distinctions, as a greater precision of knowledge than now exists will, to a certain extent, result even from a partial attainment of these objects, and will be extremely conducive, not only to an acquaintance with the influences by which these agents are modified, and with the changes they effect on the human economy, but also to the suggestion and acquisition of means by which their effects will be prevented, or be counteracted where prevention cannot be accomplished. The chief fault of distinctions drawn between *infection* and *contagion*, and at the arrangement of the various modes and kinds of these agencies, is, that both the one and the other are based upon preconceived and narrow views of their nature and operation, involving, moreover, various opinions by no means consonant with the usual procession of morbid actions. The obvious course, therefore, is to make distinctions only where differences actually exist, applying terms with precision, according either to their received meaning, or to the sense in which it is desired to receive them, and to arrange phenomena according to the relations established by close observation and candid description. In the following remarks I use the word *infection* in its *generic* acceptation, employing it according to the meaning attached to it by VIRGIL, OVID, PLINY, and other classical writers of antiquity, and by many modern authors; and applying it to whatever may effect, so as ultimately to *taint, pollute*, or *corrupt the body*. I use also the word *contagion* in the sense imposed on it by VIRGIL, PLINY, COLUMELLA, and CURTIUS—as an *infection by immediate or mediate contact*—as a *pollution by the touch*. The word *contamination* may with justice be applied to the deterioration or morbid change which takes place in the fluids of the body during the course of infectious maladies. The terms *morbid impression* and *morbid influence* will represent the change first produced, particularly on the nervous system, by the agents of infection. Although the effluvia or emanations from the sick, the secretions formed in the course of infectious diseases, and the putrid fluids in the bodies of the dead, generally act upon the living, when applied in a manner suited to the operation of each, as *animal poisons*, yet I will restrict this term to those agents which are usually thus designated.

3. From this it will appear that the word *infection* is here employed in its most extensive application; and that the words *contagion, contamination, morbid impression*, or *influence*, are used to express the chief modes in which it takes place, and the chief states in which it may exist. Receiving therefore *infection* as the generic appellation, the other terms represent *species* arranged under it. In other words the frame may be infected — 1st, by the *morbid impression* of agents — *internal* or *self-generated*, or *external and mephitic*, the infection being limited to the individual, and incapable of propagating its kind. — 2ndly, by the *contamination* produced by animal effluvia, the infection being capable of propagating itself in certain ascertained circumstances, and of spreading to the healthy from those affected by these agents. 3rdly, by the *morbid impression* or *contamination* of specific emanations and secretions, the infection presenting certain specific effects, or disseminating and perpetuating specific maladies.

4. The various influences and agents, by which the human frame is infected throughout, come under one or other of these modes of operation. They consist chiefly or miasms or exhalations from vegetable matters in a state of decay; of unwholesome or noxious ingesta; of effluvia from dead animal matter; of the emanations from the healthy in confined situations, and from the sick in several diseases, and in the various circumstances favourable to their accumulation or concentration; of septic matters arising from animal decay; and of palpable or more or less consistent secretions. But several infectious agents may be associated in their operation. The miasms or exhalations from decayed vegetable matter, or from the soil, &c. may be conjoined with the effluvia from animal substances. Some of them may act directly, or in the vicinity of their sources only, as those derived from vegetable and animal decay. Others not only operate in this way, but also through the medium of substances which imbibe and retain them in a sufficient quantity to be injurious. They admit however of certain general propositions being stated with respect to them; and of the following arrangement, with reference both to their nature and effects.

a. Infecting agents consist almost entirely of decayed or diseased organised substances, and of animal emanations or secretions.

b. Those agents which proceed from the decay of vegetable substances or principles, although they infect the frame exposed to their sources, are yet incapable, when unaided, of producing those states of action generating a seminium, or morbid principle by which they may be propagated from the sick to the healthy.

c. Organic bodies in a state of decay or disease, and animal secretions, *infect* the human frame chiefly during states of predisposition or susceptibility of the frame, certain only of which states are ascertained.

d. The *morbid actions* produced by infectious agents generally assume specific forms according to the nature of the agent, so that the agent being known, its effects may be predicated; and on the other hand, the nature of the agent may be inferred from the form and characters of the existing effect.

CLASSIFICATION OF INFECTIOUS AGENTS.

Class of Agents.	*Order of Agents.*	*Species of Agents.*	*Diseases resulting therefrom.*
I. NON-DISSEMINATING, AND NON-PERPETUATING INFECTIONS. *Idio-infectants.*	i. *Miasms or mephitic vapours—Endemic Infection—acting through the air.*	1. Miasms from decayed vegetable matter aided by moisture, in temperate ranges of atmospheric heat.	Catarrhal fevers. Rheumatic attacks. Intermittents. Enlargements of the spleen, and torpid states of the liver.
		2. Exhalations from absorbent, or deep, exuberant, or marshy soils, suspended in atmospheric humidity at temperate grades of warmth.	Intermittents. Remittents. Simple dysentery. Simple cholera. Bilious fevers. Obstructions and other diseases of the liver and glandular organs.
		3. Miasms or vapours from decayed vegetable matter, or from marshes and rich, deep, and humid soils, at high ranges of temperature.	Inflammatory, bilious, and gastric fevers of both a remittent and continued type. Diseases chiefly of the abdominal viscera.
	ii. *Unwholesome and poisonous ingesta* —Infections occasionally epidemic.	Unripe, diseased, or decayed grain. Diseased or putrid fish or flesh. Water containing putrid animal matters, &c. &c. &c.	Ergotism. Gangrenous ergotism. Asthenic and chronic diarrhœa. Dysentery. Scurvy and scorbutic dysentery. Mucous, gastric and putro-adynamic fevers.
	iii. *Self contaminating agents*, or morbid matters formed in a part, afterwards contaminating the system generally.	1. Cancer. Fungo-hæmatoid disease, &c.	The carcinomatous and fungo-hæmatoid cachexy.
		2. Purulent, sanious, or other morbid secretions carried into the circulation.	Acute hectic. Low remittent, and adynamic states of fever, often attended by phlebitis or purulent deposits in the viscera or joints.
II. CONDITIONALLY PERPETUATING INFECTIONS. — *Contaminating infections.*	i. *Animal effluvia.*—Producing diseases propagating the same or similar maladies in favourable circumstances. *Conditionally and consecutively infectious*, chiefly by means of diffusive and impalpable emanations.	1. Effluvia from animal matter or from vegeto-animal matters during decomposition, aided by humidity.	Adynamic or pernicious remittents. Continued fevers. Adynamic dysentery. Cholera. Gastric, mucous, or enteric fevers.
		2. Emanations from living bodies in close or unventilated situations.	Adynamic putro-adynamic, and malignant fevers. Malignant dysentery.
		3. Emanations from the secretions and discharges of the sick confined in close apartments, &c., and the direct application of these secretions.	Erysipelas. Hospital gangrene. Phlebitis. Puerperal fever.
	ii. *Animal secretions and septic animal matters.* —Infectious chiefly by contact, or inoculation of a palpable matter; *chiefly sporadic.*	1. Morbid secretions in recently dead bodies.	The irritative fever, or malignant effects produced upon opening recent bodies, by the morbid secretions poured out in serous cavities.
		2. Animal matter in a state of putridity or decomposition.	Diffusive or disorganising inflammation of cellular parts. Inflammation of lymphatics of veins, &c.
		3. Morbid secretions communicated from the lower animals by contact or inoculation.	Glanders. Farcy malignant pustule and other affections arising from contaminating diseases in the lower animals.
		4. The poisonous bites of insects and reptiles.	General vital depression, and septic disorganization, or solution of the vital cohesion of the tissues.
III. SPECIFIC INFECTIONS. — Infections immediately or mediately disseminating and perpetuating their kinds, by a morbid impression, or by contamination, or by both. Capable of retention and communication by Fomites.	i. *Impalpable specific infections* of susceptible persons. Diffusive or volatile infections, frequently epidemic.	Emanations from the secretions, excretions, and surfaces of persons already affected. — Propagating their kind by a diffused and impalpable effluvium, or vapour.	Epidemic and exanthematic typhus. True yellow fever. Pestilential cholera. Pertussis.
	ii. *Palpable specific contagions.* Consistent contagions.	A specific secretion or virus from the seat of disease perpetuating maladies always presenting the same characters.	Rabies. Syphilis. Gonorrhea. Scabies. Yaws. Sivvens. Frambœsia. Purulent or Egyptian Ophthalmia. Cow-pox. Pellagra. Porrigo.
	iii. *Infectious both diffusive and consistent.*—Often epidemic.	Diffusive and impalpable emanations, and consistent secretions, from the bodies of the infected, either of which may produce the same disease.	Chicken-pox. Scarlet fever. Small-pox. Measles. Malignant puerperal fever. Plague.

5.—I. THE SOURCES OF INFECTION.—According to the extensive sense in which I have employed the term infection, its sources or agents are numerous and diversified. They may be arranged —1st. Into Idio-infectants, or those which produce diseases incapable of perpetuating their kinds, unless other causes be superadded; — 2d. Into those which produce maladies which may be propagated under favourable circumstances — or into *conditionally perpetuating infections*; — and 3d. Into *Specific Infections*, or those which produce diseases which perpetuate their kinds, both immediately, and mediately by *fomites*.

6. i. — Under the FIRST CLASS may be arranged those infections derived from (*a*) endemic sources; — (*b*) from the ingesta; — and (*c*) from morbid matters generated in the body, and conveyed into the circulation, thereby contaminating the whole frame. The diseases proceeding from these sources never give rise to the infection of the healthy, unless they are modified in their characters by superadded causes, or unless they are materially influenced by determining or consecutive circumstances. — A. The *miasms or exhalations from the soil* produce a great variety of diseases according to the temperature and humidity of the air, and the quantity or activity of the miasms floating in it; but the diseases thus produced will not propagate themselves. If, however, other causes are superadded, — if the persons labouring under disease from this source be confined in ill-ventilated apartments, or breathe a close air

loaded with animal exhalations, the disease may change its form, and assume some one or other of those which arise from the *second class* of causes — from animal effluvia, — and thus become consecutively and conditionally infectious. I could adduce numerous instances of diseases, originating in local or endemic sources, becoming thus infectious. Livy adduces more than one instance of it; and numerous others are furnished in the medical histories of wars and campaigns; but unfortunately the circumstances connected with them have rarely been recorded with precision, and sometimes not even with impartiality.

7. *B.* — The *use of unwholesome food* infects the body with disease, which is not capable of being communicated to the healthy under ordinary circumstances. But persons affected with diseases from this source may be exposed to additional causes which will change the character and course of these diseases, and give rise, as in the foregoing instances, to a truly infectious property. It is well known that unwholesome and scanty nourishment will produce scurvy, scorbutic dysentery, and low or adynamic fevers. These fevers are generally not capable at first, or as they immediately proceed from this cause, of propagating their kinds, but they frequently assume this character, owing to states of the air, to insufficient ventilation, and to the manners and imperfect civilization of those amongst whom they occur. Proofs of this were furnished in Italy and France during 1815, 1816, and 1817, — at Marseilles in 1812, and 1813, — in Ireland during various periods, particularly since the commencement of this century, and even in the present day in some parts of England. The disease which prevailed in the Penitentiary, and which was so ably described by Dr. Latham, and the fevers now prevalent among the poor, are proofs of the infectious characters which distempers thus originating generally assume. I am convinced that the low dietaries assigned to the poor in the Union workhouses, in connection with crowding, and with imperfect ventilation, in many of them, have been a chief cause of the present prevalence of typhus throughout the country. And although the infectious visitation may not have reached those who have been the prime movers in the iniquity, yet it may overtake some of them with no measured retribution. Persons who require the aid of the Poor Law have usually as respects food or drink, and sometimes as regards both, lived fully or intemperately; and when they are subjected to a diet, altogether insufficient for the continuance of health even in the temperate, low fever, which readily propagates its kind among the predisposed, and on occasions favouring communication, soon makes its appearance. This result the more certainly follows, when numbers are similarly circumstanced, and placed in buildings possessing no thorough ventilation or perflation of air. The only recently erected Union workhouses which I have seen, are most improperly planned, inasmuch as they have windows only looking into the interior of the Court, of which they form three of the sides. This is shameful if it proceed from ignorance, and flagitious if it be done designedly. We can hardly suppose architects so ignorant of the most generally acknowledged principles of their art, as to neglect ventilation where it is most required. Are we therefore to consider that they have been controlled by those who have sacrificed feelings of humanity to the expediency of political economy?

8. — From considerable observation and reflection, I infer that disease may take place sporadically, or from local causes; and owing to various circumstances acting either in close succession or coetaneously, the circulating and secreting fluids, and even the soft solids, may be so changed during its course, as to emit an effluvium contaminating the surrounding air and thereby infecting many of those who breathe this air in a sufficiently contaminated state; and thus the disease will be propagated to several, and from these to others, especially under favourable circumstances of temperature, humidity, electrical conditions and stillness of the air, and of predisposition on the part of those who come within the focus of infection. Thus diseases may become *infectious*, and, when aided by the constitution of the air, and other circumstances, even *epidemic*. After thus spreading for a time, they may cease or entirely disappear with the circumstances which combine to propagate them.

9. *C.* — The *Self-contaminating agents*, or morbid matters formed in a part, and afterwards infecting the system generally, but seldom, perhaps, give rise to disease, capable of propagating its kind. When sanious or purulent matters are carried into the circulation, the consequent alteration in the blood gives rise to phenomena closely resembling typhoid or low fevers in many cases; but I do not believe that the malady thus produced will infect the healthy, unless under circumstances peculiarly favourable to infection, as in puerperal females, in the wards of lying-in hospitals. I think it extremely probable, that the sanious fluid constituting the lochia may be absorbed or imbibed from the surface of the uterus, particularly when the uterus contracts imperfectly, or when the discharge is retained or accumulates, and when vital power is much depressed, and that the consequent pollution of the circulating and secreted fluids will give rise to an effluvium which may produce puerperal fever in a female recently confined, if she come within the focus of infection. It is not improbable, that erysipelas also may be excited by the effluvium emitted from a person thus diseased. I attended with another practitioner, a case of dangerous puerperal fever of this kind. A lady visited this patient, and leant close to her mouth, so as to hear her faint articulations, but perceived her breath so offensive, and felt it produce so unpleasant a sensation on her own face, as to induce her to remove to a greater distance. This lady continued to perceive the unpleasant odour, and to feel the sensation in the face until the following day, when she experienced chills with swelling and redness about the nose, extending over the face: — a complete attack of erysipelas followed.

10. That the morbid secretions of persons affected with low fever, consequent on the absorption of morbid matters, into the circulation, will infect the healthy frame when inserted into a wound or under the cuticle, or even when applied to a mucous surface, is by no means improbable. I have seen the most dangerous diseases arise, from the inoculation, and even from the contact of the fluids during the examination of the bodies of females, who had died of puerperal disease, caused

by the passage of sanious or morbid secretions into the circulation, as well as by the influence of an impure air. The danger of infection or inoculation from these cases is great in proportion to the shortness of time that has elapsed from dissolution; and it is particularly great when the body still retains some of its warmth. The above considerations and facts prove that, although the several orders of agents comprised under the *first class* produce merely a sporadic form of infection, or infect merely those exposed to their sources, and give rise to diseases generally incapable of propagating their kind, yet the concurrence of additional causes or influences, during their course, will develope a disease capable of being communicated to the healthy under circumstances of predisposition, and in similar modes, as well as by the same media, as the diseases produced by the class of agents next to be noticed.

11. ii. *The second class of agents.* *A.* Effluvia from *animal exuvia* and *animal secretions and excretions* directly occasion those forms of disease which infect the healthy by contaminating the surrounding air. The particular *form* or *species* of malady thereby produced, depends much upon the nature of concurrent causes — upon the concentration or accumulation of the effluvium, — upon its sources, — upon its admixture with miasms from decayed vegetable substances, — upon the temperature, humidity, and electrical states of the air, — upon the susceptibility or state of predisposition of those exposed to it, — and upon pre-existing disorder. The operation of some of the sources of infection falling under this head has been disputed. Dr. Bancroft, by a laboured special pleading, has denied the injurious influence of putrifying animal substances; but much depends upon the temperature in which this process takes place, the concentration of the emanations arising from this source, and epidemical states of the air. When the temperature is low, and ventilation is preserved, no very acute or sudden disease results from this cause, particularly to those accustomed to it, although a gradual loss of health generally follows its continued or frequent influence. But in other circumstances, particularly when aided by concurrent causes and marked susceptibility, febrile diseases of a low or adynamic form, and of an infectious character, where free ventilation is not preserved, generally appear. The emanations from the lower animals, as horses and cattle, crowded in ill-ventilated places, produce infectious diseases, not only amongst them, but also in those of the human species, who may breathe for some time the air which is thus contaminated. Livy, Dionysius of Halicarnassus, and Orosius, mention a destructive disease which appeared in Rome 464 years before Christ. Livy states that it occurred in Autumn from the crowds of countrymen and herds of cattle received within the walls of the city; that it was aggravated by the infection arising from the crowded state of the close buildings, by the heat and want of rest; and moreover that the disease was propagated by contagion and by the attendants on the sick. The same historian records that, in the 325th year from the foundation of Rome, a remarkable drought and famine extended throughout the Roman territory: that diseases followed, first invading cattle, and afterwards infecting the rustics and lower classes of people, and then extending to the city. That disease of an infectious nature may be developed in the lower animals by their confinement in close or ill-ventilated places has been proved on numerous occasions; and there is no reason to doubt the possibility of the distemper thus produced being communicated to the human species. A number of horses shut up in the hold of a transport will generate glanders in some of them, the morbid secretion of which will communicate a similar disease to persons employed about those which are affected, especially if it come in contact with the mucous surfaces. It may be stated as an axiom, that the foul air generated by the crowding of many persons or animals into a confined space, even in health, but more especially in disease, as in the wards of hospitals, &c.; or by a few persons only in the same apartment, if their diseases be attended by copious discharges, will infect those who breathe it in a state of predisposition, with low fever, dysentery, &c.; and that the persons thus infected will communicate the malady to others similarly predisposed. Although animal effluvia infect the healthy chiefly by their diffusion in the atmosphere, yet the infection will not take place, unless near their sources, or in situations where they become concentrated. Much, however, will depend upon the predisposition or susceptibility of persons exposed to them.

12. *B.* Certain maladies do not perpetuate themselves by effluvia or by an impalpable emanation, but by *the contact of the secretions formed in their course;* and these secretions will seldom induce disease unless they be inoculated, or come in contact with a mucous surface. Other secretions, particularly from diseased animals, when brought in contact even with the unabraded skin, will sometimes produce serious distempers. Instances of this fact are furnished by the malignant pustule, and by other maladies already noticed. The inoculation of putrid animal matters, and the bites of poisonous reptiles, infect or contaminate the whole frame in a sufficiently remarkable manner, the former agents producing a low, irritative, or adynamic state of fever; but the diseases thus produced seem incapable of propagating their kind, unless by the inoculation of morbid matters formed in their course, or taken from the body after death; and then the effects will probably vary with the previous state of health of the person thus infected, and with various concurrent circumstances.

13. iii. *Of the Third Class of Infectious Agents.* It is unnecessary to add any thing to the statement contained in the classification of these agents, which I have attempted. The impalpable emanations and consistent secretions of which they consist, produce specific forms of disease, whether they operate *directly* or by various *media*, or *fomites.* But, although the chief characters of these maladies are uniformly preserved, in all of them, during their transmission, yet several of them are much modified by concurrent causes, by the circumstances, or existing states, of the affected, and by endemic and epidemic influences.

14. II. Of the Proofs of Infection, *or the circumstances proving a disease to be capable of propagating its kind.* It has been asserted by some recent writers, that the doctrine of infection, by contact or otherwise, is a comparatively modern invention. These assertions have been made by

persons possessed neither of sufficient medical learning nor practical information, to attach any degree of importance to their opinions. It has been satisfactorily shown by Dr. Yeats in this country, by Dr. Marx in Germany, and Dr. Omodei in Italy, that the doctrine of contagion was recognized by the ancient Egyptians and Jews, by the Greeks and by the Romans: and that it was equally believed in during the middle ages, although the notions of many respecting it, even among professional writers, were often loose and inaccurate It is unnecessary to adduce proofs of the acquaintance of the ancients with contagion, as this has been done so satisfactorily by the writers just mentioned. Some evidence also on this subject will be found in the article Epidemic Influence. Indeed the matter would never have been questioned, had not commercial men, in order to remove some impediments in the way of their traffic, properly imposed for the public good, employed persons to write in favour of their interests; but with an ability and success quite commensurate with the truth and justice of their cause. The question, however, as lately agitated, is not so much the existence or non-existence of infection or contagion in any circumstances, and as respects all diseases, for proofs of the possession of these properties by certain maladies are so incontrovertible, as not to be doubted. It is principally with respect to the infectious nature of pestilential epidemics, as plague, yellow fever, and epidemic cholera, that the subject has created so much interest and discussion at the present day. When we consider the extent to which the dread of the importation of these maladies impedes commercial undertakings, in connection with the little consideration human life receives in the prosecution of commercial objects, it is not likely that the contingent importation of infection will operate in such a manner, as long to prevent attempts at the removal of existing salutary restrictions; although the *proofs* as to the existence of an infectious property in these distempers, are considered quite conclusive by all candid inquirers.

15. i. There are various circumstances which, singly or conjoined, *prove* a disease to be *truly infectious*, or capable of propagating itself. — 1st. The arrival in places which are healthy of persons from districts in which a disease is prevalent, and the spread of such disease soon afterwards in the previously healthy place. — 2dly. The extension of such disease in this place, in proportion to the intercourse between the affected and the healthy. — 3d. The greater prevalence of such disease amongst persons who devote themselves to its alleviation, as amongst medical attendants, nurses, and the friends of the sick. — 4th. The absence of any other cause to which the malady may be attributed, the soil, the climate, the season of the year, the weather, neither singly nor conjointly, serving to account for it. — 5thly. The immunity obtained by seclusion and by avoiding communication with the sick and those who have visited them, as well as by the careful exclusion of all substances which may have imbibed and retained the emanations from the affected. — 6thly. The success of measures taken to prevent the extension of the malady, as the early removal of the sick to places where communication with the healthy is prevented. Besides these, there are other proofs, which are even more conclusive. When we perceive the healthy become affected with a malady, soon after proximity to, or contact with, a person labouring under a similar malady, or after having been exposed to substances which have imbibed the effluvium from the sick, as bed and body-clothes, &c., the evidence of infection from these sources, although not amounting to complete certainty, yet nearly approaches it. Instances of contagion by *inoculation*, and by immediate or direct communication with the sick, are sufficiently numerous in respect of several maladies, and are familiar to all: and the evidence of infection by substances which have imbibed a morbid effluvium or secretion — by *fomites* — is not less strong, although it is in some cases not so conclusive, and hence it has been more frequently impugned. It has been satisfactorily shown to all candid minds, and numerous instances have occurred to my own observation, of a disease having been conveyed in the clothes of a second person, and communicated to a healthy individual. That this has occurred with respect to certain maladies acknowledgedly infectious, cannot be disputed by the most captious objector. The only questions admitting of doubt are, — to what diseases should this capability of propagation be extended: and for how long a period, and under what circumstances, may the infectious effluvium be thus retained and conveyed. Some answer to the first of these questions will be obtained by what is hereafter to be advanced; as to the second, it is impossible, from the nature of the subjects involved in it, to furnish precise information. There is every reason however to state, that the body-clothes or bedding, used by a person while sick of an infectious disease, may communicate the same malady several or even many months afterwards, if they have been shut up from the air; and I have known several instances of a disease being conveyed from the sick to the healthy, the person, who has been the medium of communication, having walked a distance of upwards of two miles in thus conveying it.

16. ii. *Of the media by which infectious agents are communicated to the healthy frame.*—*a*. The *miasms* or *mephitic vapours*, exhaled from the sources already enumerated, are evidently suspended, and rendered active, by the humidity of the atmosphere, in the situations in which they are disengaged: for it has been repeatedly shown, that these miasms are active in proportion to the grade of atmospheric humidity, and to the circumstances which augment that humidity. Their presence in the air brings them in contact with that part of the animal economy, presenting the greatest extent of surface, the greatest vascularity, and the freest communication with the circulating system. Although the atmosphere, aided by humidity and a moderate or high range of temperature, is the usual medium of infection, especially in respect of those maladies, which emit an offensive effluvium or emanation; yet there are other media which observation has shown to be not infrequent means of communication. Numerous substances imbibe, retain for a considerable time, and convey, the invisible or *infectious* emanations, as well as the palpable and *contagious* virus, or consistent secretions of the sick, and become media, by which infection is conveyed from one person or from one country to another, between

whom a greater or less distance is interposed. Of the various materials, which may thus be the means of transmitting infectious diseases, animal productions, particularly woollen and hairy substances, bedding and body-clothes, furs and feathers, have the greatest disposition to imbibe and to retain the morbid effluvium. The *length of time*, during which the morbid *seminium* may thus be retained and still be operative, has never been accurately determined. Probably the period varies with the disease from which it proceeds. There can be no doubt that it depends much on the exclusion of the atmosphere, and upon the temperature to which it has been exposed.

17. *b*. When infection is produced by substances which imbibe and retain the morbid effluvium or secretion, it does not arise from actual contact with the substance which is thus the medium of communication, unless it conveys a more or less consistent virus or secretion. The substance imbued with the morbid effluvium retains it whilst shut up from the air for a longer or shorter period, but more or less readily imparts it when exposed to the atmosphere, which now becomes the infecting medium. Even the clothes of an attendant upon a person labouring under an infectious disease, will retain the morbid emanation much longer than is generally supposed. There are few who will dispute the fact of infectious diseases being often communicated in the clothes of medical men, and other attendants on the sick. I have known several instances of small-pox, puerperal fever, and pestilential cholera, being thus propagated. I was recently called to the wife of a physician in the most malignant form of small-pox, conveyed to her by her husband whilst he was in attendance on a case of this disease at a considerable distance from his own residence. Sometime ago I was requested by a practitioner in extensive midwifery practice, to see a case of true puerperal fever. He had, within a few days, lost five patients from this malady. I asked him to consider whether he might not have been the medium of communicating the disease to most of them. Before my attendance on this case terminated, he expressed his conviction that he had communicated the malady to four at least of the six. Similar instances have been mentioned to me by other obstetric practitioners. — I am convinced of having conveyed the infection of pestilential cholera in my clothes, in two instances.

18. *c*. The infection or contamination caused by ingesta, or by substances used as food and drink, is generally not so rapid in its progress or so dangerous, as when the infectious agent acts through the medium of the air upon the lungs, or when it is conveyed into the system by inoculation. Some, however, of the more active poisons may be said to furnish exceptions to this law, but they hardly come within the present category. Unwholesome articles of food generally infect the system by a succession of morbid changes requiring more or less time for their developement; and much of their baneful effects is counteracted by the vital influence and resistance of the stomach, and by the changes produced by the gastric juices. Still, in proportion to the injurious nature of the substances received into the stomach, will the organic nerves be morbidly impressed, or the chyle and blood contaminated, by the noxious fluids or matters absorbed from the digestive canal, or both kinds of disorder be induced, the effects varying with the activity of the injurious agent, and the duration or repetition of its operation. A morbid emanation, which would produce an immediate effect upon being inspired with the air, will be quite inoperative when received into the stomach mixed with the saliva: and a morbid secretion or virus, which would be followed by the most dangerous results when inserted under the cuticle, may be swallowed with impunity. The matter of small-pox will produce no effect when conveyed into the stomach of a person, who will be readily infected by the effluvium or the virus of the disease; and the same obtains with respect to other contagious maladies. The immunity from the one medium of communication, and the ready operation of the others, are accounted for by the structure and functions of the organs and parts to which the infecting agent is applied. From this the ignorance of pathological principles displayed in the silly and disgusting attempts to prove certain maladies to be non-infectious or non-contagious, by tasting or swallowing the secretions to which they give rise, will be sufficiently evident.

19. *d*. In cases of general infection of the frame, resulting from a local source of contamination existing in the body itself, the media of infection may be readily inferred. Cancerous, sanious, or purulent matters may be formed in a part of the body; and as long as nervous power, and vital resistance are not materially depressed, either the mischief is limited, or attempts are made at throwing it off; but as the system becomes weakened, the disease extends, absorption takes place, the morbid matter carried into the circulating vessels vitiates the blood; and hence arise imperfect and disordered secretion and excretion, insufficient digestion and assimilation, and a general infection of the fluids and solids of the body.

20. *e*. The *effluvia* or *emanations* from a number of persons even in health, shut up in a confined space, or in ill-ventilated apartments — from the lower animals similarly circumstanced — from the sick in crowded wards, &c. — and from those with infectious or contagious diseases, generally operate almost entirely through the medium of the atmosphere, and with an activity in proportion to the humidity of the air, and to the accumulation of the noxious effluvium, relatively to the susceptibility or degree of predisposition of those exposed to its action. But as all the emanations from the sick consist in a great part of watery vapour, even a dry air, if it be not quickly renewed, will at length become so moist, as to be soon as injurious as that which was already humid. Moisture favours the developement of infectious emanations, increases the activity of all of them, and heightens the predisposition of persons exposed to them. Experience has shown that the emanations from the sick seldom infect the healthy, whilst the air is dry, cool, and freely renewed; that infectious diseases seldom occur or appear only sporadically in such circumstances; and that these diseases generally prevail or become epidemic in warm, humid, and stagnant states of the atmosphere. The crowded wards of hospitals, ships of war and transports, generally continue healthy, as long as dryness and freshness of the air are preserved. But as soon as these requisites to health are neglected; when the floors of the former, or the decks

of the latter are frequently washed, so as to render the air moist; the emanations from the healthy as well as from the sick readily accumulate or acquire activity. Fevers, dysentery, scurvy, erysipelas, and even hospital gangrene or phagedenic ulceration and phlebitis, will thus be developed or rendered prevalent.

21. *f.* Although there are various agents which infect the body in a certain determinate mode or medium, — as typhoid and exanthematous fevers, by the emanations proceeding from those affected by them floating in the air, — syphilis, by contact, — rabies, by inoculation, &c., — yet there are others, as arranged above, which operate in more than one, or by all these modes. There are some sources of infection respecting which we are still insufficiently informed as to the several modes or media of their action. A person on opening a recent body that has died of peritonitis, may have a pustular or erysipelatous inflammation of the skin of his hands, with smart fever produced, although there has been neither puncture nor abrasion of the cuticle, and if either has existed his life will be placed in the utmost jeopardy. Mr. KIERNAN informs me that he has even seen, from the inspection of cases of this description, very severe constitutional disorder produced in those who had never touched the bodies which were examined. In these instances, the effluvium exhaled from the peritoneal cavity or from other internal parts, upon first exposing them, must have infected the system.

22. III. THE EFFECTS, OR THE DISEASES, PRODUCED BY INFECTION vary with the sources and modes of infection, with the concentration or intensity of the infectious agents, and with the predisposition or susceptibility of the persons exposed to them. Certain of these agents produce a determinate effect, or a specific form of disease, particularly those comprised under the third class. — *A.* It has been supposed, that the terrestrial miasms or mephitic vapours, emitted by marshes and other sources of malaria, produce only intermittent and remittent fevers. Some writers, however, have contended that true yellow fever, and even plague, also spring from these sources, aided by the influence of high ranges of temperature and an epidemic state of the air. That terrestrial miasms are capable of producing, under these circumstances, pernicious or malignant forms of fever, which assume either a remittent or a continued type, according to concurring causes and the state of the patient, I will readily admit; but that they occasion either true yellow fever or plague, is an assumption founded on preconceived and fallacious views, which every circumstance connected with the origin and pathological relations of these maladies fully disprove. (See Art. PESTILENCES.)

23. That malaria, however, produces a wider range of diseased action, than has been long supposed, I will allow; for I agree with much that has been advanced by Dr. MACCULLOCH on this subject, and believe, that the less concentrated states of terrestrial exhalation, particularly in low grades of atmospheric temperature, will give rise to several diseases usually imputed to other causes, — as to catarrhs or catarrhal fevers, rheumatism, neuralgic affections, sciatica, obstructions of glandular organs and premature decay. When terrestrial exhalations are concentrated or rendered more active by a warm and humid air, bilious inflammatory remittents, gastric or mucous fevers, cholera, dysentery, and visceral diseases will frequently result, according to the existing disposition or states of those exposed to them.

24. *B.* The contaminating effects of unwholesome kinds of food and drink frequently declare themselves in specific forms and modes. Ergotism, gangrenous ergotism, scurvy, scorbutic dysentery, adynamic dysentery, &c., are illustrations of this. On many occasions, however, the ingesta constitute only one of the sources of infection, or other causes concur with this in producing the effect. Mucous, gastric, and putro-adynamic fevers and dysenteries, even when chiefly occasioned by septic or diseased articles of food, or by water containing putrid animal matter, are often aided in their appearance by additional causes: when foul water is concerned in the production of septic or adynamic maladies, animal or vegetable exhalations, or both, and unwholesome food, frequently co-operate with it. The fevers and dysenteries so generally developed in armies, in besieged towns, &c., seldom proceed from a single source of contamination only. When they assume highly infectious and typhoid forms, it will generally be found, that putrid and impure food and water, exhalations from animal exuviæ, and from the surrounding soil containing numerous dead bodies imperfectly covered with the earth, famine, fatigue, and the depressing passions, first contaminate the frame; and that the exhalations from persons confined in close places, and from those first affected by those causes, heighten still further the morbid effects, until a most malignant malady is produced. It is extremely probable, that the air of a place thus circumstanced, and especially the moisture floating in it, may become so saturated with noxious effluvia derived from these sources, as to assume a pestilential character; the infection extending to nearly all who breathe it, but becoming less remarkable, as the distance from the focus of infection increases. Hence it is, that in large, crowded, or populous cities, particularly in seasons when the temperature is high and the air humid, and is already contaminated by the circumstances which necessarily attach to them, and especially by exhalations from animal exuviæ and burying places, the infectious emanations from the persons first attacked by the resulting febrile maladies heighten the existing aerial contamination, produce a more marked effect, and more readily spread the malady in these places than in those differently circumstanced. During the pestilence in Rome, during 262 and 263, the air is stated by EUSEBIUS and CEDRENUS to have been so contaminated by the emanations from the sick and dead, that the dew which fell in the mornings and evenings presented a sanious or putrid appearance on the surface of objects. It is chiefly owing to this circumstance that when an infectious disease becomes very destructive, or assumes a pestilential form in crowded cities, it seldom spreads extensively in districts far removed from them, although it is generally communicated to a greater or less extent to the healthy, by those who have left the source of infection, and by *fomites;* for the circumstances favourable to the infection are there wanting.

25. That continued fevers of a low, adynamic, typhoid, or putro-adynamic character, dysentery, erysipelas, hospital gangrene, phlebitis, puerperal fever, diffusive or disorganizing inflammation of cellular parts, and the diseases enumerated in

the Classification, as the results of the various kinds of contaminating or infectious agents comprised under the *second class* of my arrangement, arise from these sources, may appear paradoxical to many. But an extensive examination into the subject will show that animal affluvia produce those diversified effects, according to the nature of the effluvia, to concurrent circumstances, and to the peculiarities of the persons affected; and that the resulting maladies perpetuate their kinds, when the conditions favouring this occurrence are present.— That morbid actions, often of a most dangerous and malignant kind, follow the inoculation of morbid secretions and septic animal matters, although these secretions may not have been taken from a person labouring under a disease generally recognised as being infectious or contagious, has been evinced on various occasions, and shown even by experiments. Much, however, in these cases, depends upon the health of the persons who may be thus inoculated. The general persuasion that diseases usually recognised as contagious, alone can be communicated in this way, is by no means correct, for the range of infection by inoculation is much wider. Indeed, I consider it as a pathological principle, that morbid secretions and septic animal matters, from whatever source, will, if applied to an abraded or divided living surface, or allowed to remain in contact with a mucous, or even with the external surface, give rise to some one of the maladies assigned in the Classification to this order of agents; and that the morbid matters generated by these maladies will produce similar effects in others, if applied in the same way, provided that a predisposition to the infection exists. This predisposition manifestly consists of depressed constitutional power, and weakened vital resistance, often in connection with disorder of the digestive organs, and sometimes with general cachexia.

26. The maladies which are produced by the third class of agents, or by *specific infections and contagions*, are, with few exceptions, so generally recognised as the results of the operation of these agents, as to require no remark. The diseases that may be viewed as exceptions to this mode of origin by some writers, whose powers of argumentation and knowledge of the sources and course of morbid actions have secured for them but slight reputation with competent judges, cannot be more particularly alluded to in connection with their sources at this place.

27. C. *The diseases produced by infectious or contagious agents may be modified or aggravated, by superadded or consecutive causes.* — This is especially the case with those febrile maladies, which arise from endemic sources, and from animal effluvia. The emanations from the sick of these maladies, if allowed to accumulate around the patient, particularly where several are confined in ill-ventilated places, will aggravate the disease, impart to it new characters, and an infectious atmosphere may be thus generated capable of producing a modified, or even a different, but generally a much more malignant, malady, than that which originally existed. The aggravation of diseases by the accumulation of the emanations from the sick, or from any other source productive of infection, obtains generally. On the other hand, free ventilation exerts a beneficial influence, and prevents the contamination of the circulating fluids, as well as the depression of vital power that would otherwise result.

28. Humidity and dryness of the atmosphere have much influence upon inflectious maladies. The former not only gives activity to infectious agents, but also aggravates their effects, and predisposes the human frame to their operation. Infection is, in the first instance, thereby favoured and accelerated; and it is subsequently aggravated in the whole progress of its resulting phenomena. Dryness of the air, on the other hand, either prevents infection, or delays the development of its effects. The depressing passions, fear, and whatever lowers vital energy, are most influential and powerful concurring and aggravating causes of infection, both before it is fully developed, and during the course of its effects.

29. IV. OF THE PERIOD WHICH ELAPSES FROM THE FIRST IMPRESSION OR OPERATION OF INFECTIOUS AGENTS, TILL THE DEVELOPMENT OF THEIR EFFECTS.—The period which elapses from exposure to the agents of infection until the development of their effects, varies remarkably in its duration, as respects not only different infectious maladies, but also different persons exposed to the impression of the same agent. This period has been denominated the *latent* period and the period of *incubation* by French pathologists. I have, in the articles DISEASE and FEVER, called it the *formative*, *premonitory*, or *precursory* stage, or the period of *premonition*, because the changes taking place in the constitution during this stage are productive of the subsequent phenomena, and are generally manifested by certain symptoms, attention to which may often prove of essential service in the prevention or treatment of the consecutive disease. The *duration* of this period has been differently stated by different writers, as respects almost every infectious disease. In some of these diseases it is quite indeterminate; but, as regards others, it is more uniform. — *a*. The precursory period of diseases which proceed from terrestrial or paludal emanations, varies from six or seven days, to as many months. From data obtained by Dr. GREGORY, it would appear, that of a number of persons exposed to malaria proceeding from the same source at a precise period, thirteen days were the shortest, and thirty-nine days the longest, duration of this period; and that in the greatest number, agues and remittents were developed on the 20th and 22d days after infection. In some cases, where I had an opportunity of observing this period, remittent fever appeared in some six or seven days, and in others a few days later, after exposure to the cause. Dr. MARSH infers, from numerous instances furnished him in Ireland, that this period may be protracted to eight or nine months.

30. *b*. The duration of the formative period in *typhoid fevers* has not been observed with sufficient precision. Dr. HAYGARTH declared that the minimum was seven days, and the maximum seventy-two days. Dr. BANCROFT inferred the minimum period to be thirteen days; but the observations of Sir W. BURNETT, Dr. MARSH, and others, prove that the period is much shorter. Dr. MARSH, indeed, endeavours to show that the febrile rigor may succeed almost immediately to the exposure to the infectious effluvium. But in many of the instances which he adduces, there is every reason to suppose that a previous exposure to infection had occurred, *that* which seemed to have made the morbid impression having only been a consecutive or determining cause of the disease. Dr. WILLIAMS thinks that this period may extend

from a few hours to a few weeks, or perhaps to a few months. I have stated, that it may not continue beyond twenty-four hours in the worst forms of these fevers, and that the most common duration is from three to fourteeen days. This agrees with some observations which I have lately had an opportunity of making. Dr. Gregory considers that the medium duration of this period in these fevers is ten days.

31. *c.* The precursory or formative period in *measles* generally continues from seven or eight, to fifteen or twenty days. Dr. Bateman states it to vary from ten to fifteen days. Dr. Gregory from eight to twenty-one days. Dr. Williams remarks, that the time which this poison might remain latent has been determined to vary from ten to sixteen days. This agrees with the observations of Dr. Heberden and of Dr. Hue. — Dr. Home, who first tried the inoculation of measles, observed that the eruption appeared on the sixth day afterwards. The experiments of inoculation in measles by Vogel, Monro, Tissot, Cullen, Speranza, and others, furnish no additional information on this subject.—M. Guersent is of opinion that *hooping-cough* appears five or six days after infection. I have stated that it is generally from five to nine days, or even longer, after exposure to infection, that the cough commences.

32. *d.* In *scarlet fever*, the formative period varies in duration from one, to twenty or twenty-five days. Dr. Williams considers that it continues from a few hours to about ten days. Dr. Binns assigns two days as the shortest period; Dr. Withering three or four days; and Dr. Heberden and Dr. Frank five days; Dr. Blackburn believes that the period varies from four to seven days; and Dr. Willan, that it rarely continues longer than six days. The duration of this period depends much on the character of the epidemic. Dr. Maton observed, in one epidemic, this stage prolonged to twenty-five or twenty-six days. In a most malignant case of the disease, which I recently attended, infection was produced by some of the secretion from the mouth of a patient having been conveyed by the hand to the glans penis of a different person. Most violent asthenic inflammation and excoriation extended thence over the genitals, to the groins, abdomen, and inside of the thighs.

33. *e.* In *small-pox*, the duration of the precursory period varies from six, to twenty or twenty-one days. When the disease appears in the natural way, or by the medium of the air, Dr. Gregory thinks twelve days to be then the usual period.—When small-pox is *inoculated*, the eruptive fever commences seven days afterwards, but it may be delayed a day or two longer. Indeed, cases occasionally appear, in which this period is either shorter or longer than that now stated.

34. *f.* In *plague*, the precursory period may be very short. Sir Brooke Faulkner has mentioned some cases, in which the attack seemed to follow almost immediately, or within a few hours, upon the impression of the infectious effluvium. Some writers have stated this period to vary from two to fifteen days, five days being its medium duration. The disease has occurred on the fourth day after its inoculation. — *True yellow fever* usually appears from two to twelve days after infection; but it may take place in a few hours after the impression of the morbid effluvium, when concentrated. — In *pestilential cholera*, the precursory period varies from one to six days, according to my own observations; and this agrees with the statements of others. This period may, however, be somewhat shorter or much longer than now stated.—True or *malignant puerperal fever* usually occurs from one to five days after infection, but it may be delayed beyond this period.

35. *g.* The time that the infection of *erysipelas* takes to develope itself has not been accurately determined. Dr. Williams thinks that it may vary from two to fourteen days. In the instance above alluded to, and in some others that I have seen, the period was not longer than thirty-six hours. In the various forms of infection proceeding from the inoculation of morbid matters, or from injuries during the dissection of recent or of putrid bodies, the constitutional effects are usually manifested within three days, sometimes in the course of a few hours and very rarely after four days.

36. *h.* The morbid secretions productive of the various forms of *venereal disease* evince their effects at various periods, between one or two days and two months. The *gonorrhœal* affection generally appears much earlier than the *syphilitic;* the former most frequently showing itself from two or three days to ten or twelve, — the latter from six or seven days to two or three weeks.

37. *i.* The virus of *rabies* takes a longer time in developing itself, than any other infectious agent. There can be no doubt of the precursory period of this malady being sometimes prolonged much beyond what is generally believed, although the very long intervals stated to have elapsed in some instances are quite apocryphal. There are, however, well attested cases of two years having passed from the insertion of the virus until the appearance of the malady. Instances of from four to twelve months having thus elapsed are by no means rare. The *shortest* period of premonition in rabies may be stated to be twenty-one days. In the greatest number of cases, the disease appeared from thirty-one to sixty-three days after the inoculation of the morbid secretion.

38. *After the first impression* of an infectious agent, until the development of its effects, or during the whole of this percursory period, the change produced in the economy presents certain general features, which are of the utmost importance to recognise, and to estimate aright. These changes are not materially different in the different infectious maladies: they vary, however, in intensity as much as in duration; but they often possess very nearly the same characters, which always manifest the production of a more or less noxious effect upon the economy — as depression of nervous and mental energy, and of all the manifestations of life. These manifestations are, however, severally depressed in different degrees, in different maladies, during this period; and certain organs experience this effect more than others, as well as betray a specific or peculiar mode of affection according to the nature of the infectious agent. In those distempers which proceed from the more intense or concentrated agents, and in which the precursory period is short and severe, the effect produced upon the nervous system is generally immediate and remarkable. Not only are the physical functions depressed and embarrassed, but the mental and moral powers are remarkably weakened or nearly

annihilated. In true yellow fever, in plague, and puerperal fever, the patients become indifferent to their fate, and care not for the most intimate relations. The sensibilities are not merely blunted, they are almost destroyed; and a similar effect is observed in many other infectious maladies, although not in so remarkable a degree. Much of the calmness displayed by persons in this, as well as in the more advanced stages of these diseases, results not so much from a philosophical or stoical suppression of the sentiments and emotions, as from a generally impaired power of the organic nervous system, and a consequent impairment or loss of the general sensibility, and of the cerebral energy. Hence the physical change is often such, that those parts of the frame which are the most intimately related to the manifestations of mind, or which either minister to them or are their instruments, are more or less incapable of discharging their offices.

39. V. THE SYMPTOMS OR INDICATIONS OF INFECTION vary remarkably in the rapidity of their production, in their intensity, and in their numbers, forms, and modes of grouping. But it is of importance that they should be recognised by the physician. When the infecting agent is intense, as when a concentrated animal effluvium or an accumulated emanation from the bodies of the sick is directed upon a susceptible person, then the effect may be as instantaneous as electricity, as well as most intense. In some rare cases of this kind, as in plague, and in other pestilential maladies, life may be destroyed in a few hours by the morbid impression which it has been quite incapable of opposing, and against which it has been unable to react. I have seen the emanations from typhoid fever, from yellow fever, and from pestilential cholera, immediately produce sickness, vomiting, pain, sinking and anxiety at the epigastrium, faintness, oppression at the chest, remarkably weak pulse, headach, and general vital depression, with pale countenance and shrunk surface; and from these the patient has never rallied, the symptoms increasing in severity, and others supervening, until death has occurred in a very few hours.

40. Where the agents are less active or less concentrated, or where the predisposition is not so great, a much longer time is taken in the development of the changes constituting the precursory period of infectious maladies; and in the majority of those, the vital powers resist the further progress of these changes in that particular direction, and a salutary *reaction* is established. In many instances, little or no complaint is made after exposure to infectious agents, although a morbid impression has actually been made by them. In some only a slight *malaise,* or an indefinite feeling of indisposition, indicative of depression of vital power, only is complained of. In others, the depression is much more manifest, and is attended with a weak or slow pulse, or with unusual acceleration of the pulse upon slight exertion; with chills, alternating with flushings or heat of skin, depression of spirits, and pallor of the countenance, great weakness of the joints, and impaired power of the digestive, secreting, and excreting functions. When infection is produced through the medium of the respiratory organs, the earliest effect that is observed is a feeling of constriction or oppression in the chest, or at the præcordia and epigastrium, attended by frequent sighing, gaping, forced and deep inspirations, and by uneasy sinking, depression, or nausea, and sometimes by pain at the stomach, and by vomiting. The natural and acquired appetites and desires are diminished or nearly abolished; nausea is readily excited by food; and the bowels are either costive or relaxed, or easily acted upon by purgatives. All the organic functions are impaired, and the sexual desire suppressed. The patient feels debilitated and fatigued; complains of headach, vertigo, or confusion of ideas; is morose, low spirited, sluggish, indolent, or incapable of exertion, or of directing his attention long to any object: he readily perspires, and his breathing becomes short and quick, on the least exertion. His sleep is unsound and unrefreshing, and he wakens, complaining of lassitude or of pains in his back and limbs. All the cerebro-spinal functions are weakened or disordered. The countenance and skin are unusually pale, sallow, or unhealthy; more rarely red; the eyes are languid and deficient in brilliancy; the breath is fœtid or cool; and the tongue is often loaded—occasionally red or flabby. The urine is sometimes pale and copious; and the cutaneous surface is dry, cool, and harsh or constricted. These symptoms are sometimes so slight as to escape particular attention, and are often insufficient to induce the patient to confine himself. They are frequently much more intense, without being different as to kind; their intensity increasing more or less rapidly, until a sensation of cold running down the back, with formication, chills, or rigors, supervene, indicating the approaching development of the malady.

41. When infection is produced by inoculation, the more immediate effects are somewhat differently manifested, according to the nature of the morbific agent; and, in those maladies which require a long precursory period for their full formation, several of the above symptoms are either altogether wanting, or are so slight as to escape detection. In some instances, persons actually infected may complain but little, or may experience merely slight debility, inaptitude for exertion, various dyspeptic symptoms, and depression of spirits. At last some consecutive or determining influence comes in operation, and the infectious agent, thus reinforced, soon produces its full effects.

42. In some instances, the premonitory period is characterised by remarkable mental depression, by a reserved manner, and by the anticipation of an approaching calamity or even death. When a person who has been exposed to infectious agents, particularly those which are liable to become epidemic, is possessed with the idea of his impending dissolution, this unfortunate termination generally takes place. This symptom, more, perhaps, than any other, indicates a dangerous functional lesion of the nervous system.

43. *There are various circumstances which favour or retard the development of infection.*— Several of them have been already noticed (§ 27.). Many of those which favour the development of infection, not only render the consequent disease much more severe than it would otherwise have been, but also complicate that disease, and impart to it a fatal tendency. Exposure to wet and cold, unpleasant or distressing intelligence, a debauch, excessive fatigue, and exhaustion from

any cause, during the precursory period, will not only accelerate the effects of infectious agents, but also give rise to inflammation, or congestion, or obstruction of some vital organ. This often occurs in measles, scarlet and typhoid fevers, hooping-cough, small-pox, &c. — Dr. Marsh justly remarks, that a principal reason of the danger and fatality of fever amongst medical practitioners is, that, during the latent period, they make an effort day after day to discharge their laborious duties, until at length they are reluctantly compelled to yield; the disease having gathered strength in the same proportion as they have made strong, but ineffectual, efforts to resist it. A slight illness may be prevented by a strong effort, but a severe one is thereby greatly, often fatally, aggravated, and this is not the case merely in respect of fever, but of every malady produced by infection. The circumstances which retard or prevent the development of infection will be considered hereafter, when the pathological views here stated will be applied to practical purposes.

44. VI. The Manner in which Infections and Contagions invade the Economy, and their immediate and direct Effects, have lately excited some discussion. And let it not be supposed that the subject is devoid of importance. For correct views respecting it will lead to the adoption of means for the protection of the system, both at the time of exposure and in the period which more immediately follows it, that will often prove successful in counteracting its earlier effects, or in rendering the course of the disease more mild. — *A.* It is now about twenty years since I endeavoured to show, by anatomical connections, by functional relations, and by intimate observation of the effects produced by the more energetic morbific agents, that their impression is first made chiefly upon *the organic nervous system,* although the change or effect thereby produced, necessarily soon extends to the vascular system, and even to the circulating fluids; and that this takes place when the infectious agent is inserted into a wound, as well as when it is inhaled into the lungs with the air. At the same time I endeavoured to show that certain agents may more especially affect the circulation by their imbibition or absorption into the blood. This is more especially the case when the infectious agent is received into the alimentary canal with the solid or fluid ingesta, or when it consists of morbid secretions formed in an organ or part admitting of their passage into the circulation. There can be no doubt of the respiratory organs being generally immediately affected by all those agents which are conveyed through the medium of the atmosphere. The cutaneous surface is sufficiently protected from the operation of the impalpable emanations constituting the most common and the most numerous infectious agents. The digestive mucous membrane, although less guarded than the cutaneous surface, is still less exposed than it to their action. It is chiefly, therefore, through the medium of the respiratory surfaces that these agents make their direct impression. On these surfaces the air may be said to undergo a process of digestion — certain elements or portions of it entering in the circulation, combining for a time with the circulating fluids, and promoting their perfect sanguifaction and assimilation; and from those surfaces certain gaseous fluids and elementary principles are given off, which have served their purposes in the economy. There is every reason to infer, that during this process, noxious matters floating in the air, or dissolved in the moisture of the atmosphere, produce a morbid impression upon the nerves supplying these surfaces, and upon the respiratory organs generally; and that this impression is more or less rapidly transmitted throughout the organic nervous system, — the other organs and general systems of the body, more immediately dependent upon this system, soon manifesting the effects thus produced. At the same time, the noxious emanations, thus conveyed to the lungs in the course of the respiratory functions, most probably affect the condition of the circulating organs and of the blood itself, — both these orders of effects taking place co-ordinately, or either of them in a more or less special manner. That certain infectious agents impress the organic nervous system directly and chiefly, is shown by the suddenness of the effects; by the sensations experienced at the time of exposure to those agents, especially to the emanations conveyed in the air; by the sense of constriction and oppression produced in the chest; by the frequent and forcible efforts made to dilate or fill the lungs, as if the impression of the infectious emanation had impaired the vital resiliency of these organs; by the offensive odour frequently perceived at the time of infection; by the sickness, fear, and alarm instantly afterwards felt; and by the other phenomena already enumerated.

45. *B.* Next to the impression and change in the nervous system of organic life, the alterations in *the circulating organs and fluids,* consequent upon infection, deserve attention. When infectious effluvia are inhaled into the lungs, the weak action of the heart soon indicates the depression of this system. The impulse of the heart is feeble, slow, or irregular, and oppressed. The pulse is weak, soft, compressible, or small — sometimes irregular. It indicates a want of tone; and when the infectious agent has acted with much intensity, absolutely or relatively, the sensation imparted by the artery suggests the idea that the contractility of the coats of the vessel is much impaired. From this defect of the contractility and tone of the blood-vessels arises, during the precursory period of diseases produced by the more energetic infections, the remarkable tendency to congestion of those parts of the circulating system, and of those vessels, which are the most removed from the influence of the heart's action. Hence the congestions of the spleen, of the portal vessels and hepatic veins, and of the sinuses within the cranium; and hence the retarded circulation through the lungs, and the fulness of the auricles and sinuses of the heart, giving rise to the sense of oppression at the præcordia and in the chest, and to the frequent sighing and forced inspirations attending this stage of disorder.

46. The effects produced by infection on the *blood* are not so immediately, or at least not so sensibly, evinced, as those induced in the functions of organs actuated by the organic nervous system. The blood may, however, be affected without the alteration being perceptible to the senses; and changes in the appearances of this fluid are usually visible, before alterations in its constitution can be detected by chemical tests or analysis. The pathological conditions of the blood during the earlier

stages of the diseases consequent upon infection have not been sufficiently observed, and far less satisfactorily investigated. Those which have been described are the results of prolonged or intense morbid action, probably aided in some cases by treatment and regimen. I have given, in the article Blood, a full view of those alterations, and explained their sources. But the subject, with all its interest and importance, has not since received any further elucidation. The state of vital depression, immediately produced by infectious agents, generally precludes the abstraction of blood, and the opportunity of observing its states. I have, however, seen some instances of blood having been taken from a vein during this state, owing to a misinterpretation of the headach, pain at the epigastrium, and oppression at the chest then complained of, and to the epidemic disposition to vascular depletion so prevalent amongst practitioners, excited and promoted as this disposition was by inexperienced writers, who inflicted their crudities and inanities upon the public, as well as upon the profession, soon after the commencement of the present century. In most of these cases the blood flowed with difficulty, was of a very deep or dark colour, and produced syncope or great depression upon the loss of a few ounces. It coagulated rapidly, and separated into a very dark, large, and soft coagulum, which sunk in the serum; this latter being small in proportion to the clot. In some instances the separation was very imperfect, the coagulum being gelatinous; and occasionally no separation took place, particularly when the powers of life were remarkably depressed. The blood taken at the commencement of the cold stage of agues often presents the same appearances, but generally in a less degree. These appearances indicate rather the vital conditions of this fluid derived from the organic nervous system supplying the vascular system and vital organs, than any change in its chemical constitution. It is not probable that the *hæmatosine* is materially altered, or that the saline ingredients and albumen have undergone any diminution, as the circumstances upon which these appearances depend have not been sufficiently long in operation to produce these effects. The *fibrine* is, however, changed or diminished; this substance evincing, by its attraction and cohesion, the state of vital or nervous power. When the fibrine contracts slowly, firmly, and so as to form a firm clot, and allow the free separation of the serum, or to give rise to a buffy or cupped surface of the coagulum, the nervous and vital powers are unimpaired, and vascular action is increased, and generally increased in proportion as this state of the coagulum becomes more remarkable. When, on the other hand, the fibrine adheres quickly, but imperfectly; when the attraction between its molecules is weak, and consequently, when either no coagulum is formed, the blood assuming a gelatinous consistence as it cools, or when the coagulum is loose and soft, with merely a slight separation of the serum, this latter either surrounding it in a small quantity, or partially, or altogether covering it, the constitutional powers may be considered as greatly reduced; and, although the circulation may be accelerated, its tone and energy are much impaired, the vital contractility of the coats of the vessels upon their contents presenting a weak *antagonism* to the action of the heart.

47. The occasions on which the blood seems to be more immediately contaminated by infectious agents, are, first, when a specific virus or morbid secretion is inserted into a wound, or beneath the cuticle; and secondly, when putrid or septic matters are similarly applied. The period which elapses between the inoculation of a specific virus, and the development of the constitutional affection, however, by no means shows that the immediate operation is upon the blood, and that this period is required for the production of morbid changes in it. If we examine the subject closely, we can arrive at this conclusion only, — that the morbid matter affects first the vital conditions and actions, and ultimately the intimate organisation of the part to which it is applied—converting the appearances and sensible properties of the part to states somewhat similar to those characterising itself; and that the contamination thus produced, soon extends, either by its immediat effects upon the organic nerves supplying the vessels of the part, and consecutively on the blood or by the imbibition or absorption of the morbid matter, or by both these channels, to the whole body, affecting more or less the blood, the secretions, and the soft solids. That the organic nervous system is the chief channel by which the first change induced in the part is communicated to the whole body, is shown by the circumstance of the constitutional effect being frequently as great whilst the local change is slight, as afterwards when it has become fully developed. Although the precise channel of primary infection cannot easily be demonstrated in cases of infection by inoculation, yet the ultimate effects, as respects both the solids and fluids, are sufficiently apparent. The facts and illustrations contained in the articles Blood (§110. *et seq.*), and Fever (§18.526.), render further remark on this topic almost unnecessary. That the blood undergoes, at an earlier or later period of most infectious diseases, a remarkable change as respects its appearances and sensible properties, is sufficiently established. In what the chemical or intimate change may consist, has not been shown by analysis. There can be no doubt, however, that in the advanced progress of some of these maladies, the saline principles of the blood are either diminished in quantity or altered in their combinations, as shown by Dr. Stevens. Indeed, this may be considered as a necessary consequence of the abstraction, during the disease, of the usual saline substances contained in the food. When the quantity of *chloride of sodium* used by an individual in the twenty four hours is considered, in connection with the fact that the whole of it passes into the circulation, we must expect a remarkable diminution of this salt, or of its base, in the blood of persons who have been but a few days affected by febrile or infectious maladies. The earliest changes, however, produced upon the blood are manifestly those of its vital conditions.

48. It is very reasonable to suppose that the influence exerted by the organic nervous system upon the circulating organs and vessels throughout their whole extent, and thence upon the contents of these vessels, will alter the appearances and conditions of these contents, as itself becomes altered by the influence of infectious agents; and that the effect thus produced upon the circulating fluids will reciprocate the morbid affection, and heighten disorder in the system more immediately

and directly impressed, — that, in short, nervous influence, which first experiences the morbid change, in communicating this change to the vascular system and circulating fluids, soon undergoes a further alteration, owing to the changes it has itself produced in these fluids. In some instances, however, and especially when putrid matters are applied to a wound, a more rapid contamination of the circulating fluids may be inferred. When these matters, or when morbid secretions, or blood in an advanced period of malignant or putrid diseases, are injected into the circulation, it is but reasonable to infer that the effects will be more immediate, and that they will be in most respects similar to the morbid conditions characterising the advanced stages of the malignant or putro-adynamic maladies produced by self-perpetuating infections or contagions. The interesting experiments of GASPARD, MAJENDIE, LEURET, and HAMMOND have fully established the truth of these inferences, as shown in the article just referred to.

49. *C.* The morbid impression made upon the organic nervous system, and the change induced upon the circulating organs, by infectious agents, necessarily *affect the secretions and excretions.* As the secreting and excreting organs are actuated chiefly by the organic nervous system, and as the vital manifestations of this system are remarkably depressed by infectious agents, the functions of these organs must consequently be more or less impaired soon after infection. It is chiefly owing to this circumstance, that the blood becomes altered in the progress of infectious diseases. In the article already noticed, I have fully shown that the imperfect performance of the functions of depuration is a chief cause of the morbid states of the blood; and that, as these functions are impaired in proportion as vital power is diminished, so must the secretions and excretions be disordered both in the early and in the advanced stages of infectious maladies. In the former of these stages, even the period of premonition, the disorder of these functions is often manifest, but they are diminished rather than vitiated. In the advanced stages, they are prominently vitiated as well as diminished; and sometimes, even when the vitiation is most remarkable, they are sufficiently abundant or even remarkably copious.

50. *D.* The *alterations produced in the soft solids by infection* are the latest in the procession of the consequent morbid phenomena, and vary remarkably with the nature of the infectious agent. Some of those agents produce certain determinate or specific effects upon the tissues. Thus the effluvium of small-pox affects the skin and mucous surfaces especially; — that of scarlet fever, the throat, digestive mucous surface, skin, and the membranes of the brain; — that of measles, the respiratory and cutaneous surfaces, &c.; — that of plague, the lymphatic system and glandular organs; — that of erysipelas, the integuments and cellular tissue; — that of syphilis, the absorbent glands, the periosteum, the skin, bones, and joints; and so on, as respects most kinds of infectious diseases. — These alterations are, however, much modified, or additional lesions are developed, by consecutive changes or influences; by the temperament, predisposition, or previous disorder of the patient; or even by the treatment, — as when certain complications appear from these or other circumstances, at the commencement, or during the course, of infectious fevers. Amongst the changes induced in the soft solids by infectious agents, the most important, and evidently the most intimately dependent upon the state of vital manifestation and the conditions of the circulating and secreted fluids, are the discolouration and the softening of membranous and parenchymatous structures. This discolouration and softening, as observed soon after death, are perfectly independent of incipient dissolution of the tissues, and are generally great in proportion as the infectious or contagious nature of the agent is remarkable. The general loss of the vital cohesion of the tissues is often so great, that even the most firm and coherent structures are torn with ease; the substance of the heart, and muscular parts, also participating in the change. (See art. FEVERS, § 527.)

51. VII. THE CIRCUMSTANCES WHICH FAVOUR INFECTION are numerous, and it is of importance that they should be recognised and well understood by the physician. These circumstances may be grouped — first, into those which are *intrinsic*, which concern the individual, or are proper to the recipient; — secondly, into those which are *extrinsic*, or which concur or co-operate with the infectious agent. — *a.* The circumstances proper to the recipient of infection are numerous, but the chief only of them can here receive particular notice. There is a *susceptibility* to infection from birth, which, in respect to some infections, diminishes with age, or is entirely exhausted or destroyed by the disease which it produces. This destruction of the susceptibility to infection is remarkable, as regards the exanthematic contagions, yellow fever, and hooping-cough; and, although it is not universal, yet the exceptions are very rare. In certain infectious maladies, as continued and typhoid fevers, the susceptibility increases with the progress to puberty, and diminishes gradually from the twenty-fifth or twenty-seventh year to old age. The danger, however, increases with this diminution, if infection actually takes place. Although typhoid fevers do not entirely exhaust the susceptibility to their infection, they manifestly weaken it. When a person has escaped infection, upon the first or the earlier exposures to several infectious maladies, he will generally continue to possess an immunity, unless circumstances should occur to increase his predisposition; for the infectious emanation produces a more sensible and marked effect on the economy, on the first occasion of exposure to it, than subsequently unless long intervals have elapsed between the periods of exposure. It is thus that several members of the same family so often escape, notwithstanding the rest are labouring under infectious maladies, — the susceptibility to them diminishing with the frequency of exposure, unless concurrent causes or influences reinforce the infecting agent.

52. The kind of susceptibility, which disposes to infection, varies much with different infectious maladies. In some, as typhoid fevers, youth and the prime of life are predisposing circumstances; and yet, fear of the disease, fatigue, exhaustion, and other causes altogether of an opposite character, have a similar influence, and concur with it. In others, as yellow fever, the seasoning, pernicious, and malignant fevers of warm climates, persons in the prime of life, and of the most robust

and plethoric constitutions, are the most liable to infection; whilst remittents and agues usually affect, in preference, the more debilitated, and persons of a weaker and more delicate frame. Most of the maladies, which are capable of propagating themselves, exhaust the susceptibility to reinfection. The chief exceptions to this are—venereal affections, plague, and purulent ophthalmia; whereas, the infections which are incapable of propagating themselves, unless other causes be superadded, particularly those which consist principally of emanations from decayed vegetable products, leave after them an increased disposition to reinfection. A person who has once had an attack of periodic fever, is more susceptible of infection upon exposure to malaria; and a smaller dose of the poison will take effect.

53. Of the other sources of susceptibility to infection, the most important are — fear and the depressing passions, disorder of the digestive organs, general ill health, and whatever impairs the powers of life. All infectious agents produce a morbid impression on the nervous system, and contaminate the circulating and secreted fluids, with a rapidity, and to an extent, *cæteris paribus*, according to the weakness of vital power and resistance. When the nervous influence and vascular tone and action are insufficient to oppose these agents, the infection then takes effect; the morbid influence extends; the circulating fluids are either early contaminated, or soon become deteriorated; and thus the whole frame is brought, not only under the influence of, but is actually polluted by, the disease.

54. There are other circumstances which predispose to, or increase, the susceptibility of infection; but they are so well known, in respect both of their nature and modes of operation, that they need not be noticed at this place. They are chiefly *extrinsic* to the body; and either precede, or are nearly coetaneous in their action with, the infectious agent. Those which *subsequently come in aid* of this agent, and aggravate, modify, and complicate its mode of operation and effects, have already been alluded to (§ 27.). They will be found more fully discussed in the articles DISEASE (§ 61.), and ENDEMIC AND EPIDEMIC INFLUENCES.

55. VIII. THE MEANS WHICH PROTECT FROM INFECTION, AND COUNTERACT ITS IMPRESSION AND OPERATION, are of the greatest importance, as respects both the science of the physician and the safety of the community. These measures may be divided into — 1st, Those which protect by excluding and destroying infectious agents, or by preventing communication with infectious persons or things; — and, 2dly, Those which are prophylactic, and which guard or fortify the individual against the impression or contamination of infections and contagions. — *The first of these classes of preservative means may be subdivided into* — 1. Quarantine, and the separation of the infected from the healthy; — 2. The exclusion of infected articles, or the destruction of all infection existing in them; — and, 3. The dilution and destruction of the infections floating in the air, or in any other medium.

56. *A. The separation of the infected from the healthy* is the chief means by which a distemper can be prevented from extending. This can be enforced only by governments, and local authorities, when a pestilential or infectious epidemic threatens a country or district. To the neglect or imperfect accomplishment of the measures which belong to quarantine, is chiefly to be imputed the extension of pestilential maladies, particularly in countries bordering on the Mediterranean. The difficulty, however, of putting these measures in force, and the facilities of evading them, especially by the transmission of infected clothes and other fomites, and as regards continental countries having an extended boundary, or populous cities or towns having an extensive communication, are so great, that numerous instances of their infraction must occur, and the chances of the introduction of these maladies be thereby increased. The extension of plague, yellow fever, and pestilential cholera, in different countries, has been entirely owing to the neglect of quarantine and of other means of prevention. If these means could be duly enforced in all their relations, not only those, but other infectious maladies, as typhoid fevers and small-pox, might be either entirely excluded from certain localities, or remarkably limited in their spread, particularly where the situation and boundaries of a place favour the application of these means.

57. Next to the exclusion of infected persons or things from a place, the removal of those first infected to suitable places, where they may be properly treated, and where the extension of the disease is duly guarded against, is of importance. The habitations of infected persons should undergo the processes of cleansing, fumigation, &c., about to be noticed; and all intercouse between the infected house, and those adjoining, ought to be prevented, or placed under certain restrictions. In large commercial towns, and in populous districts, where a strict quarantine or sanatory measures, calculated entirely to prevent a malady from extending, cannot be maintained, the mischief resulting from the attempt will be greater than the benefits which will arise to the community. But where they may be enforced, owing to the nature of the locality and other circumstances favourable to their due maintenance, they should be adopted, notwithstanding the temporary losses, or even distresses, of the place thus sequestered; for the advantages of the few should give place to the safety of the many.

58. As intimately connected with all regulations of quarantine and seclusion, *the duration of the period which elapses from the impression of the infectious agent, to the development of the disease*, should be taken into consideration. On this subject, the information which I have attempted to give (§ 29.) will be found useful. It is obvious that a person may be exposed to a source of infection in one place, and may travel a long distance during the period of formative or smouldering action, and not experience the developed malady until after his arrival in a healthy locality, where he may introduce the infection. In the present day of rapid conveyance, a person may carry an infectious malady, which he has caught in London, to any of the remotest parts of the kingdom, or from almost any European country to this.

59. It is of no less importance to know *the time which a person who has been ill of disease capable of transmission from one to another, retains the power of infection*; but this is a matter of still greater difficulty, even than the knowledge of the duration of the precursory period. The body

itself, probably, loses the power of transmitting a malady, as soon as convalescence is so far established as to admit of free exercise in the open air. Probably a fortnight after the commencement of recovery from most infectious maladies, the power of spreading them has ceased. Where a disease has been communicated at so late a period as this, there is every reason to suppose that the clothes have been concerned in its communication. It is, however, most difficult to assign a precise period with reference to any infectious malady, as its duration will entirely depend upon the personal habits of the individual, upon the ventilation and means of purification resorted to during illness as well as during convalescence, and upon the care taken with his clothes and person. Amongst the lower classes, infection probably continues longer to attach itself to the person than the period now named, owing to circumstances peculiar to them; and there is every reason to believe that it may continue in their apartments or dwellings even weeks and months afterwards, unless disinfecting means be carefully employed.

60. *B.* In many situations, and in several distempers, *the chances of infection by fomites* are much greater than by communication with the sick. — Articles of bedding, feathers, furs, body-clothes, &c., which have imbibed the effluvium of the affected, readily transmit most of the infectious diseases of this country, as well as the pestilential maladies of other countries, to very distant parts. It is astonishing, how long woollen and silken bed and body-clothes will retain the effluvium, so as to affect the healthy by it, when closely packed together, or excluded from ventilation. The animal miasm, which the clothes worn in dissecting rooms have imbibed, will be sensibly perceived many months afterwards, if they have been put in a close place, immediately after they were saturated with the foul air. The necessity of subjecting these articles to ablution, to free ventilation, and to other means of purification, is sufficiently obvious; but, by the lower classes, and even by other persons, all precautionary measures, even those which merely consist of common cleanliness, are most flagitiously neglected, although amongst them those measures are the most requisite. The crowded, low, close, and dirty state of their apartments, and the neglect of ventilation by them in all circumstances, and especially during disease, demand a stricter enforcement of purification, or disinfection, amongst them than elsewhere. Before articles from them or other infected sources are introduced amongst healthy predisposed persons, they should be subjected to the disinfecting agents about to be noticed; and to the perflation of the air in suitable situations, or in places from which the public are excluded.

61. *C. Disinfection.*—During the continuance of an infectious malady in a family or place, it is the duty of the inmates of the one, and of the authorities of the other, to put in force certain *measures of disinfection;* particularly when, owing to the general prevalence or nature of the malady, it may not be deemed requisite to remove the sick to places suitable for their seclusion and treatment. In all circumstances, however, disinfecting means should be employed, as tending, not only to protect the healthy, but also to aid the infected. For it is obvious, that it is much to the advantage of the latter to have the air and clothes, in which they are confined, frequently renewed, and the morbid effluvium removed or counteracted, than to be subject to its concentrated influence during the course of the malady. To dilute, therefore, or to destroy, the infections floating in the air, or attached to any other medium, is a duty we owe both to the sick and to the healthy.

62. *a.* Amongst disinfecting means, a *perflation of pure dry air,* and the abstraction of all sources of humidity, are the most universally beneficial and applicable. These alone prevent several maladies, particularly those which proceed from the sources of infection, ranged under the first and second classes of these agents (§ 4.), from propagating themselves; and when they can be fully enforced, they prevent the extension of most of those distempers, which always proceed from specific infection and contagion. Whatever may be the sources of the morbid effluvium or emanation, dilution by a free ventilation will either weaken or destroy it—at least, so far as to cause it to fail to produce its usual effects. This result will be more certainly obtained when the air is dry. High ranges of temperature, by increasing the humidity of the atmosphere, favour infection, if a very free ventilation is not preserved; and cold, although preventing infection when there is a free circulation of air, often also promotes it, owing to the means used to prevent currents of cold air. This is frequently evinced by the evolution or propagation of infectious diseases in the close wards of hospitals and other places, during winter and spring.

63. *b. Various means* have been resorted to for *the destruction* or *neutralisation of infectious emanations,* especially during the prevalence of destructive epidemics or pestilences. In the desire to establish the efficacy of recently introduced disinfectants, the older means have been undeservedly depreciated. Although the former are the most efficacious, yet it follows not that the latter were devoid of all disinfecting powers. The advantages derived in former times from *fumigations* by camphor, benzoin, myrrh, tar, and terebinthinate substances, and by numerous aromatic, fragrant, and stimulating drugs, were owing to more than one circumstance. These means not only inspired those who used them with confidence, but also in some measure neutralised the operation of the infectious emanation. The fumes from them, and from other exciting and fragrant substances, often counteracted the impression made by the morbid emanation upon the nervous system, by preventing the depression it would otherwise have produced. On this account they may still be resorted to with advantage in some circumstances, particularly in cases of casual or short exposure to infectious emanations, or when it is desired to counteract those which are the less virulent and not generally diffused. When judiciously employed, many of these substances aid the recovery of the sick, especially when the disease is attended by much depression of vital power. Until the discovery of Labarracque's disinfecting fluid, and of the uses of the chloride of lime, they were the chief means that could be employed in the chambers of the sick; those which are next to be noticed, being, from their acrimony, suited chiefly to uninhabited houses.

64. *c. Acids* have long been in use as disinfecting agents, under the impression that they possess the property of decomposing infectious

emanations, or at least of diminishing their virulence. With this idea, the once popular nostrum, well known under the name of "*Thieves' vinegar*," was brought into notice, and even at the present day, under the name of "*Aromatic vinegar*," it is much used by persons exposed to infection, and, I believe, often with advantage. Letters and papers brought from an infected locality are not infrequently dipped in *vinegar*; while clothes and other fomites, transmitted from a similar source of infection, are exposed to the fumes arising from the slow combustion of sulphur, or, in other words, to the action of *sulphurous acid*; but as this latter is found to be injurious to the respiratory organs, and as the powers of the former are too weak to be relied upon when acids are indicated for the purpose of disinfection, the *nitrous* and the *hydrochloric* are those principally used, although not without some risk to the inhabitants of the apartments subjected to their action.—*Nitrous acid* was first employed by Dr. JOHNSTONE and Dr. CARMICHAEL SMYTH. The latter, however, obtained the parliamentary grant for the disputed discovery; and, in 1780, employed this acid to arrest the progress of a fever which was then raging at Winchester, among the Spanish prisoners confined in that city; and subsequently, numerous ships and hospitals, which had become the seat of infection, were exposed to the same agent with success. It may be easily obtained by the combination of nitre and sulphuric acid in proper proportions; and it possesses the advantage of not requiring the aid of heat to effect the development of its fumes.

65. *Hydrochloric acid* was introduced in 1773, by GUYTON MORVEAU, for the purpose of purifying the principal church at Dijon, the emanations from the crowded vaults below having so infected the air of the building, as to render it unfit for public service. This acid was soon afterwards employed with a similar intention in the prison of the same city; and its success in this case also served to establish its reputation. But the application of heat is necessary to procure the evolution of the fumes with rapidity, from the substances from which it is usually prepared. As its use is not without some danger to animal life, it is desirable that no heat should be applied when it is employed to disinfect inhabited apartments, and that the process should be allowed to go on slowly. But, however great may have been the reputation of both the nitrous and hydrochloric acids in times past, they are rarely used in the present day—both being compelled to yield to chlorine.

66. *d. Chlorine* was first brought into notice as a disinfecting agent by M. FOURCROY, in 1791; and was subsequently employed as such, on various occasions, by Mr. CRUIKSHANK of Woolwich, and by M. GUYTON MORVEAU. It has since been used by Dr. FARADAY for the purification of the Milbank Penitentiary; an account of which was published by this celebrated chemist, in the 18th volume of the *Journal of Sciences and the Arts*. Chlorine, for the purpose of fumigating, is most readily and usually obtained, as is well known, by mixing chloride of sodium and the peroxide of manganese, and adding to them a due proportion of sulphuric acid; but as it is extremely irritating to the membrane lining the bronchi and the air-cells of the lungs, when evolved in any considerable quantity, and as it is hence totally inapplicable to inhabited apartments or wards of hospitals, the above process is entirely unavailable on these occasions. To obviate this inconvenience, M. GUYTON MORVEAU introduced a very ingenious apparatus, by which the issue of gas could be regulated at pleasure: but this and all other processes have been altogether superseded by the introduction, by M. LABARRAQUE, of the *chloride of lime* and *chlorinated soda*. There has been, indeed, much discussion as to the chemical nature of these compounds, but this is a subject not requiring notice here; practically it is of far greater importance to know that they are most powerful disinfectants, and that their success has been unequivocal in the most varied cases wherein the use of these agents are indicated. M. LABARRAQUE recommends the *chloride of lime* as the substance best adapted for infected apartments, and considers the *chlorinated soda* as more applicable to foul wounds, ulcers, &c. Both these substances, however, possess the property of preventing infection or putrefaction, and of arresting it when it has commenced; and they may both be used with perfect safety in sick chambers, in the wards of hospitals, and in prisons and other inhabited places. When it is desired to purify any of these apartments, portions of linen, steeped in the solution, should be hung in various places about the room, and the floor and walls frequently and freely sprinkled with it. Some persons, however, with more nicety than discretion, object to the use of these substances, in consequence of the unpleasant odour of chlorine, which they declare to be equally or more offensive than that of the infectious effluvium; but it should be borne in mind, that the existence of the latter is pregnant with danger to those exposed to it, whilst, in the diffusion of chlorine by means of these liquids, there is nothing pernicious to life.

67. Besides cleansing the air, chlorine, and all other purifying fumigations, will have a similar effect on the various solid substances and articles of furniture in the infected apartment. It is prudent, however, in addition to the employment of the above measures, to wash these substances well with soap and water; and as soon as the patient can be removed, the walls of the apartment should be whitewashed, and the room be well and freely ventilated, prior to its being again inhabited. All bed and body clothes removed from a patient labouring under an infectious disorder, should be at once immersed in hot water, or in a solution of an alkaline ley; and after being soaked in either for a considerable time, they should be subsequently hung out in the open air, and occasionally sprinkled with the chlorinated solution. It must not be forgotten, that the beneficial effect of chlorine will be exerted only on a limited quantity of air, and that it is by no means sufficient to correct any epidemic taint existing in the atmosphere of a district or place. When employed, however, in a limited atmosphere, this, and other disinfectants, have proved of no small advantage in checking the spread of infectious maladies; but the power which they possess, is far from being sufficient to preclude the necessity of avoiding unnecessary exposure to the sources of contagion, and of adopting preventive and precautionary measures.

68. *e.* In addition to the forementioned means, an *elevated temperature* has been recommended by

Dr. HENRY, as a powerful means of disinfecting fomites, or substances imbued with infectious emanations. The effect of heat has been principally tried in cases of *typhus* and *scarlatina;* and although its power to destroy the infectious properties of the effluvia produced by typhus may be questioned, yet the experiments of Dr. HENRY prove that the emanations of *scarlatina* are decomposed or dissipated by exposure, for an hour at least, to a temperature of 200°. And it must be acknowledged that, where heat is of itself sufficient to exert a beneficial influence upon infected clothing and other fomites, it is preferable for this purpose to chlorine, or any other fumigation, being more easily and more extensively diffused throughout the whole of the substances conveying infection. Its use is, however, limited to bed and body clothes, to trunks and packages, and other articles capable of imbibing and retaining the morbid emanation.

69. IX. PRECAUTIONS AGAINST INFECTION.— Every rational measure to avoid exposure to the infectious effluvia, whether emanating immediately from the bodies of the affected, or mediately from other sources, should be resorted to. Under this head, as strict seclusion as possible, and shunning intercourse with those most likely to have been amongst the infected, are deserving of attention. The predisposing and concurrent causes of DISEASE (see the article, §23. *et seq.* 61.) should be carefully avoided. Whatever tends, directly or indirectly, to debilitate or fatigue the body—whatever lowers its vital energy, as excesses of every description, low and unwholesome diet, and insufficient clothing, disposes to the operation of the exciting causes of infectious maladies. On the other hand, whatever tends to support this energy, and preserve in their due regularity the healthy functions of the frame, serves to render it impregnable to infectious agents. Exposure to cold, to chills, to the night-dew, to wet, and moisture; the use of cold fluids, and of cold, flatulent, and unripe fruits; should be carefully avoided. If, at any time, exposure to the night-air or to cold and moisture is inevitable, the system should be fortified against them; but the mode of doing this requires caution. It should not be attempted, unless when better means are not within reach, by wines or spirits, and, even then, these should be used in very moderate quantity; otherwise they will leave the system, as soon as their stimulating effects have passed off, more exposed than before to the invasion of infectious effluvia. Medicinal tonics and restoratives, however,— and those more especially which determine the circulation to the surface of the body, at the same time that they improve the tone of the digestive organs, and promote the regular functions of the bowels and biliary system,—may be resorted to on such occasions. For this purpose the infusions or decoctions of bark, of cascarilla, of calumba, &c., with the spirits of Mindererus, or any warm stomachic medicine, or the powdered bark, or the sulphate of quinine, or the balsams, may be taken either alone or with camphor, or with the aloes and myrrh pill, and any one of the spicy aromatics. These medicinal means are especially called for, whenever an infectious malady, of which the individual is susceptible, is present in a town or house in which the person resides; and they should be had recourse to when he retires to sleep, and in the morning before he leaves his room. He should, moreover, avoid sleeping in low and ill-ventilated apartments; and be equally distrustful of sleeping near, or even of passing through in the night-time, close and unwholesome situations and streets, particularly without having resorted to the medicinal means now suggested. (See art. ENDEMIC INFLUENCES.)

70. Care should be taken never to be exposed to the morning or night air with an empty stomach. A cup or two of coffee, and bread, previous to such exposures, will be serviceable. The stomach and bowels should be always attended to, and their functions regulated and carefully assisted; but in no case should these objects be attempted by cold, debilitating medicines, such as sulphate of magnesia, or other saline purgatives. The warm stomachic laxatives, or those combined with tonics, may be adopted with advantage, as occasion may require.

71. Particular attention ought to be paid to *personal* and *domestic cleanliness.* The surface of the body should be kept in its natural and perspirable state. The constant use of flannel nearest the skin will be serviceable for this purpose. Excessive perspirations ought to be avoided.

72. The *diet* should be regular, moderate, nutritious, and easy of digestion. Whilst every approach to low living should be shunned, its opposite ought never to be indulged in. The stomach should have no more to do than what it can perfectly accomplish without fatigue to itself, but to the promotion of its own energies. It must never be roused to a state of injurious excitement by palatable excitants, nor weakened by over distention, or too copious draughts of cold relaxing diluents.

73. The *state of the mind* also requires judicious regulation. It ought never to be excited much above, nor lowered beneath, its usual tenour. The imagination must not be allowed for a moment to dwell upon the painful considerations which the disease is calculated to bring before the mind, and least of all ought the *dread* of it to be encouraged. There is a moral courage sometimes possessed by individuals who are the weakest, perhaps, as respects physical powers, enabling them to resist more efficiently the causes of infectious and epidemic diseases, than the bodily powers of the strongest, who are not endowed with this form of mental energy. Those who dread not attacks of diseases, and who yet exercise sufficient prudence in avoiding unnecessary exposure to their predisposing and exciting causes, may justly be considered as subject to comparatively little risk from them. On all occasions, however, a foolhardy contempt or neglect of ailments, especially those affecting the stomach and bowels, ought to be guarded against.

74. During the occurrence of infectious diseases in a family, these precautions are still more imperatively required. A free *ventilation* of every apartment ought to be constantly observed, in conjunction with *fumigations* by means of aromatic substances kept slowly burning, or by the vapours of chlorinated soda or chloride of lime. If a quantity of a very weak solution of chloride of lime be put in a vessel, and some hydrochloric acid be poured upon it, and be placed in the hall, or the very lowest parts in a house, the disengaged gas will soon find its way in sufficient quantity to the higher apartments. The attendants on the

sick should particularly observe the measures now prescribed; and ought never to exert their attentions on the affected, so near their persons as to inhale their breath, or the effluvium emanating from them, without at least fortifying the vital energies in the way pointed out; and they should carefully avoid entering upon those duties with an empty stomach, or when fatigued.

75. Besides burning warm aromatic substances, and odoriferous gum-resins, in the apartments, and in those adjoining them, in which affected persons are or have been confined, solutions of chlorinated soda, or of the chloride of lime, or a saturated solution of camphor in aromatic vinegar, or in the pyroligneous acid, should be occasionally sprinkled on the floors, furniture, and bed-clothes. These means, with a thorough ventilation, and a due attention to cleanliness, will not only counteract the influence of the effluvium proceeding from the affected, and ward off its action even on the predisposed, but will also prevent the clothes, bedding, or furniture of the apartments of the sick, and the clothes of the attendants, from becoming imbued with it, so as to communicate the malady. They are within the reach nearly of all; and in the event of the extension of a pestilential infection or epidemic to any considerable town or city, if care were taken to see them put in practice, under the direction of medical councils of health, one of which should be formed in each district or quarter, much good would result from them. Keeping in recollection the principle which I have endeavoured to establish, — that the excitingcause of infection undoubtedly makes the first impression on the nerves of the lungs, — the advantages of those measures, from the circumstance of their being applied especially to this organ, must be obvious.

76. When a contagious substance has been accidentally applied to a wounded or to an abraded part, means to prevent its absorption, or contaminating influence, should be instantly resorted to, appropriately to the situation, and to the nature of the contagious principle. Ligatures above the seat of injury, and suction of the part, should be instantly employed; and ablution with a strong acid solution, — with muriatic and nitric acids, or with both, — the application of spirits of turpentine, of the nitrate of silver in substance, or in a strong solution, and similar measures, ought subsequently to be adopted. In cases of the inoculation of the virus of *rabies*, excision of the injured part should precede these means, when it can be performed. At the same time, the promotion of the digestive functions and of the constitutional powers, by the treatment already advised, will materially aid the local applications in preventing the development of disease.

77. X. Treatment when Symptoms of Infection appear. — When a person has been exposed to the sources of infection, and particularly when the symptoms I have described, indicate that infection has actually taken place, and that the disease is in the course of development, *are* there any means which will prevent its evolution, or render its course more mild, if prevention cannot be accomplished? I believe that a treatment may be adopted, which will often succeed in preventing, or in mitigating, the disease; and that these ends will frequently be attained in respect of several infectious maladies. There are some, however, which cannot be arrested after infection has taken place, or after the symptoms characterising the formative or precursory stage have appeared. Small-pox, and probably plague, scarlet fever, and measles, seem to be the chief maladies which may not be prevented from developing themselves after infection has made the full morbid impression on the economy.

78. In order to arrest the progress of infection, it is necessary to keep in recollection the conclusions as to the operation of infectious agents on the system, that may reasonably be drawn from observations, both pathological and experimental. These conclusions, as furnishing a basis for remedial indications, may be limited to the following: — 1st. That the *more immediate impression* of infections is made upon the nervous system of organic life. — 2d. That this impression is of a sedative or *depressive* kind. — 3d. That infectious agents not only *depress*, but also *modify* or *alter* the vital influence in a special manner, or, in other words, each infectious agent produces a peculiar or specific depressing effect. — 4th. That the vascular system and circulating fluids soon experience the effects of this impression; and that the action of certain infections and contagions are earlier displayed on this system, in respect of some contagions, than as regards others. — 5th. That the circulating, secreted, and excreted fluids undergo a consecutive and progressive change. — 6th. That the impression on the organic nervous and vascular systems, and the consecutive changes in the fluids, ultimately affect and impair the vital constitution and cohesion of the soft solids. — 7th. That, as an infectious agent exerts a depressing or sedative, as well as a special or peculiar, morbid impression, it is reasonable to infer, that whatever tends to increase the nervous power, will enable the energies of life to resist the morbid impression, to prevent the progress of contamination, and often ultimately to remove both their immediate and remote effects.

79. Conformably with these views, I have, on numerous occasions of exposure to infectious agents, advised a *restorative* and *tonic treatment*, with strict attention to the *prophylactic means* just advised. These should be continued for a period at least equal, and in most cases beyond, that which is required for the development of the disease. In many instances, this treatment should be preceded by an *emetic*, which may be conjoined with some warm or stimulating substance. A warm *stomachic purgative* should afterwards be exhibited; and hot diluents, with camphorated or aromatic substances, may also be given. The energies of life ought to be promoted by means suited to the habits and circumstances of the individual, particularly by tonics or light nutritious diet, and pure dry air. When the infectious agent produces, at the period of exposure to it, a sensibly depressing and morbid operation, it will be often of service to excite, as soon as possible, an artificial febrile commotion in the system, and to promote the secretions and excretions. The excitement will overcome the depressing effects, and the promotion of the secretions and excretions will preserve the blood in an uncontaminated state. Much, however, will depend upon the employment of the means appropriately to the condition and circumstances of the infected person.

80. When the primary operation of infectious

agents is characterised by great vital depression, it is surprising how large doses of tonic and restorative substances may be taken before this state is removed. A lady of a delicate constitution, usually unable to take more than two glasses of wine after dinner, without occasioning heat and discomfort, was exposed to concentrated effluvia of the exanthematic typhus now prevalent. She felt an unpleasant odour, followed by a sudden loss of strength, nausea, and all the symptoms indicative of infection in a severe form. Her spirits were depressed; she stated her conviction that she had caught the infection, although she had approached it without any dread; gave directions as to her affairs, and resigned herself to her bed. I found her, with a weak, irregular pulse, slow and very compressible. The countenance was very pallid, and the mental and corporeal depression was extreme. — I prescribed camphor in the form of pill, and the decoction of cinchona with the compound tincture, the tincture of capsicum, the chlorate of potash, and carbonate of soda, in full and frequent doses. In the intervals, wine was given freely in the form of negus, a bottle being taken in the twenty-four hours in this form. These means were persisted in for two days, before the powers of life rallied; when a free and general perspiration broke out, and restoration quickly took place.

81. Of four persons who were exposed to the concentrated emanations of typhus, three of them were seen by me soon afterwards, owing to the appearance of symptoms of infection. They were all treated upon the same principles; sulphate of quinine and camphor in full doses, and as much purified extract of aloes as was necessary to keep the bowels open, were given every three or four hours, in two of these cases. The three, thus treated, soon ceased to experience the precursory symptoms. The fourth of these exposed persons was an aged female, and hence much less susceptible of typhus infection than the three young persons who had evidently caught the infection. She escaped, but carried the infection to her son and daughter. I might adduce numerous other proofs of the success of treatment during the period which elapses from exposure to infection, till the full evolution of its effects, if my limits could admit them. But I have advanced enough to show that appropriate means will often succeed in preventing the most severe and dangerous consequences, both to the person who has been exposed to infection, and to him who is experiencing its incipient or earlier effects. (*The above article is the substance of the Gulstonian Lectures, delivered by the Author at the Royal College of Physicians, in May*, 1838.)

INFLAMMATION. — Syn. Φλόγωσις (from φλοξ, a flame), Φλεγμονὴ (from φλέγω, I burn), Φλέγμα, Φλέγμασια, Gr. *Inflammatio, Phlogosis, Phlegmone, Phlegmasia*, Lat. *Entzündung*, Germ. *Inflammation, Phlegmasie*, Fr. *Inflammazione*, Ital.

Classif. — 1. *Class*, Febrile Diseases; 2. *Order*, Inflammations (*Cullen*). 3. *Class*, Diseases of the Sanguineous Function; 2. *Order*, Inflammations (*Good*). III. Class, I. Order (*Author*, in *Preface*).

1. Defin. *Alteration of the vital actions of a part, manifested by morbid sensibility or pain, by redness, increased temperature, and swelling, generally with more or less febrile commotion of the system.*

2. *Inflammations* or *phlegmasiæ* constitute one one of the most numerous classes of disease, and appear the most frequently in practice. They are the most common sources of structural lesions, whilst they are, in their developed states, them-

selves lesions of organisation, yet originating in changes which are not at first, although they rapidly become more and more, manifest. They are thus intermediate states between disordered vital action, and change of structure; retaining, however, the characteristics of the former condition, even when they have superinduced the latter. They may be seated in any organ of the body, and in any tissue, excepting the cuticle, hair, and nails; but certain structures or parts are much more frequently affected by them than others. The phenomena characterising inflammations; the changes in the circulating and secreted fluids attending them; the effects produced by them locally and constitutionally; the remarkable variations these effects present, with the state of the system, and with the exciting causes; and the almost universal liability of the tissues and organs to their invasion; combine to impart the utmost interest and importance to the investigation of their *nature* and *treatment*.

3. In treating of this subject, I shall describe — *First, the phenomena, local and general, constituting inflammation of a sthenic form*, or as observed in a previously healthy person, with *their course, and terminations*, or consequences; — *Secondly, the varieties or states inflammation assumes*, owing to certain predisposing, exciting, and concurrent causes, to the previous condition of the patient; to morbid associations; and to the tissues affected; — *Thirdly, the causes, and pathology, or rational theory, of inflammation*; — and, *Fourthly, the treatment*, with reference to the different forms, states, and complications of the disease. Under one or other of these heads, I hope appropriately to introduce every thing of importance connected with the *causes, nature*, and *treatment* of this most important, most common, and but imperfectly understood, deviation from the healthy state.

4. I. OF THE PHENOMENA CONSTITUTING STHENIC INFLAMMATION, AND OF THEIR COURSE AND TERMINATIONS.—It is necessary, in order to form a satisfactory view of inflammation, to consider first, its phenomena, as manifested in a previously healthy constitution. It then presents characters which have been variously denominated, in order to distinguish them from those which attend inflammation occurring in previously disordered frames, as the *adhesive, phlegmonous, healthy, reparative, sthenic*, &c. — I have preferred the last of these terms, as it is more appropriate to most of the states in which this species of the disease presents itself. As *sthenic inflammation* occurs both in acute or active, and in slighter or more chronic forms, I shall describe it accordingly, but with due reference, to the succession of one to the other, — to the usual procession of the morbid phenomena of each, — to the effects upon the circulation and secretions, and to the ultimate results.

5. i. OF ACUTE STHENIC INFLAMMATION. — *A. Local Characters.* — In this, which may be denominated the truest or the most unequivocal form of inflammation, there is an *increase of the vital actions*; but this increase must be of a certain duration, and the vital actions must be altered in character as well as in degree — must be truly *morbid* — as I have contended in the article DISEASE (§ 87. *et seq.*), to constitute inflammation, and to distinguish it from the vital turgescence which is temporarily produced by local stimuli, or even by mental excitement. The true seat of inflammation is always the ganglionic nervous system and the capillary vessels of the part affected; the primary change, as will hereafter be more fully shown, originating with the former, but more fully expressed in the latter, constituent of the organisation.*

6. *Acute sthenic inflammation* commences with increased or *altered sensibility or pain* of the part, to which soon succeeds *redness*, from increased vascularity — from the enlargement of vessels. The *temperature* of the part is raised, the *functions* disturbed, the *secretions* at first interrupted, and subsequently changed; and swelling takes place. These phenomena are always present in a more or less remarkable manner, or in different proportions, and are much augmented when the system sympathises, and febrile action is developed. Neither of these constitutes inflammation when existing singly; and but four of them have generally been considered requisite to its existence, namely, *pain, redness, heat*, and *swelling*. *Disturbance*, however, *of the functions* and *disorder of the secretions* of the part, are constantly present, and are as much constituents of the disease as are those more generally conceded to it. To these, *the local symptoms*, it will be necessary more particularly to advert, before the *constitutional disorder*, consequent upon the local affection, is considered.

7. *a. Uneasy sensation, from its lowest grade, until it amounts to acute pain*, is the primary symptom following the operation of the exciting cause, or characterises that kind of excitement, or deranged influence of the ganglionic nerves forming the first series of the changes in the affected part, and it is heightened or kept up by the alteration thereby induced in the action of the capillaries. When the uneasy sensation amounts to pain, it is owing either to the degree of change in the organic nervous fibrillæ, or to the communication of the morbid excitement, originating in these nerves, to the terminations of the cerebro-spinal nerves, with which they are associated in the tissues. The pain, therefore, of inflammation originates in, or arises from, a change in the state of the particular influence exerted by the organic nervous fibrillæ of the part; this change deranging the action of the capillaries supplied by these fibrillæ, and often exciting or otherwise disturbing the sensibility of the associated cerebro-spinal nerves. That the extension, however, of the morbid change to the latter nerves is merely contingent, is shown by the slightness of the pain, or by the absence of acute pain in many cases of severe inflammation of internal viscera, particularly those which are not supplied by these nerves; and that the morbid sensation originates in the organic or ganglial nerves, and not in the cerebro-spinal, is rendered probable by the circumstance of the most acute pains which are clearly referable to the latter class of nerves, as those of neuralgia, trismus, and other spasmodic affections, not being attended by inflammation.

8. The *uneasy sensation* is the sensible mani-

---

* I may here state, that this and other views connected with the pathology of inflammation were published by me, first in 1815, and subsequently in 1820, 1822, and 1824, in the works referred to in the Bibliography. It is the more necessary to state this, as several of these views have been adopted by later writers, and brought forward with an air of originality to which they have no claims.

festation of the primary change in the organic nerves of the part, — of that change, which induces the vital expansion, or turgescence of the capillary vessels, and the consequent increased influx of blood. The morbid sensation is afterwards increased to *actual pain* by the circumstances just stated (§ 7.), and by the excessive expansion and tension taking place in that part. It differs in severity and character according to the degree of inflammation, and to the sensibility and structure of the affected part. It often consists of soreness or aching, — of pricking, itching, tickling, tension, heat, or burning, — of painful throbbing, tearing, darting, gnawing, &c.; and in parts abundantly supplied with nerves, particularly with the nerves of sensation, it is most acute. In mucous, cellular, and parenchymatous structures, the pain is rarely very severe. The substance of the brain, or of the lungs, or of the liver, or of the kidneys, is often acutely inflamed without sensibility being materially excited. Severe pain in these diseases is owing either to the extension of inflammation to the serous or fibrous structures, or to the tension of these tissues caused by the swelling of the parts they inclose. Unyielding and dense textures, as the fibrous, serous, and fibro-cartilaginous, are generally the most painful when acutely inflamed. — Pain does not always represent the true seat of the disease. In cases of partial inflammation of the substance of the brain, pain may be felt only in some remote part of a limb, or in a part of the scalp. During inflammation of the substance either of the lungs, or of the liver, or of the kidneys, or of the uterus, pain may be felt only in those ramifications of the cerebro-spinal nerves, which are most intimately related to the organic nerves of the affected part, as in the vicinity of the clavicle or shoulders, in the limbs, &c.

9. It is necessary to study, not only the severity and character of pain, with reference to the existence of inflammation, but also its types or modes. The uneasy sensation attending inflammation is generally constant; and, although often exasperated at times, it is never altogether absent. Even when no pain is complained of, as often occurs in inflammations of internal viscera, tenderness to the touch, or to pressure, is generally present. When, with continued pain, or with a sense of soreness, aching, or of throbbing synchronous with the pulse, or of heat, more or less constant, there are tenderness on pressure, and increase of the morbid sensation on exercising the functions of the part, inflammation may be inferred, even when other indications of it are absent. But the most severe pains, without tenderness, or with perfect tolerance of pressure, and especially if they are paroxysmal, and attended by complete intermissions, furnish no evidence of inflammation.

10. *b. Redness*, of itself, is not sufficient to indicate inflammation. It may arise from active congestion of the capillaries, or from a vital turgescence of only temporary duration. On the application of an irritant, redness of the part is not manifested immediately, although uneasy sensation is induced; but it soon is developed owing to the morbid excitement of the nervous fibrillæ, and like this morbid state, it is more or less permanent. The redness which has thus arisen is caused by the vital expansion of the capillaries, and by the admission of a larger current of blood into them, and of the colouring globules into a series of vessels which did not formerly admit them. The blood also, during the sthenic state of inflammation, becomes somewhat more florid than usual, in the capillary vessels. The redness is generally greatest in the centre of the inflamed part, or in that spot in which the irritation originated; but it spreads more or less, and is gradually lost in the surrounding tissues. The colour varies in depth or hue with the progress and form of inflammation; but, in the species now being considered, it is more or less florid or deep. In very vascular, or highly organised parts, the tint is deepest, owing to the more intense state of action.

11. Increased redness of a part may exist, as just stated, without inflammation. In order to impart to it essentially inflammatory characters, the vascular action from which the redness proceeds must not only be excited, but also otherwise changed from the healthy state. It must be rendered truly morbid. Stimuli or mental emotions will produce redness, but this redness is not inflammatory; it soon disappears, and gives rise to no consequences or lesions. The excitant or irritant must, from either its continued or its peculiar action, change or vitiate, as well as excite, the organic nerves of the part,—must impart to them a *truly morbid state* or influence, which similarly effects the vital actions of the capillaries, not merely exciting, but also modifying, that action, so as to give rise to effects very different from those observed in health. In this respect, chiefly, the redness of inflammation differs from simple vascular excitement, or injection or congestion. In this latter state, the vessels are distended, and contain more than their usual quantity of blood, the circulation through them varying in activity, — either rising above, or sinking below, the common grade of celerity. This state, to which only the very loose and often inappropriately employed term, *hyperæmia*, recently introduced into pathological discussions, is applicable, is, however, very different from true inflammation, although it may be readily converted into some one of the varieties of inflammation. It is unattended by that morbid state of the organic nerves of the part, upon which the true inflammatory action of the capillaries depends. However denominated, whether *congestion* or *hyperæmia* — or however qualified by the prefix *active* or *passive*, it forms no essential part, and constitutes no particular stage, of sthenic inflammation, as supposed by some recent writers.

12. If we trace *the course* of the vascular disturbance, we shall find that a contraction of the capillaries of the part follows upon the application of an irritant, and upon the change produced in the organic nerves of the part. The contraction is soon followed by a reaction or vital expansion of these vessels, an increased afflux of blood, and the other phenomena of the excited vital process. The veins receive the blood from the minutest ramifications of the capillaries, in such a manner as naturally to retard the capillary circulation in them. Consequently, when the action of the capillaries is morbidly increased, expansion of these vessels, and an excessive accumulation of blood in them, must necessarily follow; for the veins are incapable of receiving, and carrying onwards with sufficient rapidity, the quantity of blood sent to them. Owing to this circumstance, vessels pre-

viously admitting only the colourless blood, become expanded, so as to admit the red globules; and as the morbid process goes on, new vessels are probably developed; the blood also becoming, and continuing to be, more florid, as long as the sthenic action persists.

13. *c. Increased heat*, as well as augmented redness, is the result of the morbidly excited action. Experiments, however, with the thermometer, show that the warmth of inflamed parts is not so great as the sensations usually indicate.— Some writers, as HUNTER, ABERNETHY, MAYO, and others, contend, there is actually no increase of the temperature above the healthy standard; but such is not the case. The temperature of an inflamed part upon, or near the surface, is usually several degrees higher than that of parts at some distance from it; and even the deep-seated viscera experience a rise of two or three degrees, and often much more, above the healthy temperature of 98°. The existence of heat, even with increased redness, is not an unequivocal symptom of inflammation; for it may depend upon temporary or healthy excitement merely. It is necessary to be continued to indicate a morbid state of action. Moreover, it may be so slightly augmented as to escape notice.

14. As to *the source* of heat in inflamed parts, some difference of opinion has existed.— Since CRAWFORD proposed the theory of the dependence of animal heat upon the different capacities of venous and arterial blood for caloric, the warmth of these parts has been imputed by many to the quantity of blood circulating through them, and passing from the arterial to the venous state. Without occupying my limits with the opinions and discussions as to animal heat, I may remark, that Sir B. BRODIE considered, from his experiments, that the cerebro-spinal nervous system was instrumental in its production. This opinion, however, was not confirmed by the researches of LEGALLOIS, W. PHILIP, and HASTINGS. In 1820, 1822, and 1824, I published my views on the subject (see *Lond. Med. Repos.* vol. xvii. p. 370., and *Appendix* to RICHERAND's *Elements of Physiology*, p. 630.), and contended that animal heat is not the result of the difference of capacity existing between venous and arterial blood; for, as Dr. DAVY has shown, this difference is not sufficient to explain the phenomenon, although it may be subordinately concerned in producing it. I then stated, that the various causes, which modify the production of animal heat act — 1st, immediately upon the organic system of nerves; — 2dly, upon the blood; — and, 3dly, through the medium of the cerebro-spinal system, modifying the influence which this system imparts to the ganglial. I then viewed animal heat more as a vital secretion than as a chemical phenomenon, — as proceeding from, and as being controlled by, the influence exerted by the ganglial system of nerves upon the vascular system and blood; and the subsequent researches of CHOSSAT and EDWARDS obviously confirm this opinion. Conformably with this view, I have stated, in the works referred to, that the increased heat of inflammation is derived from the same source, —from the influence of the organic nerves upon the vessels of the affected part, aided by the increased circulation through the capillaries; the nervous influence enlarging these vessels, or occasioning an erectile state of them, and thereby soliciting an afflux of blood to the part. The increased temperature of erectile tissues, consequent upon irritation of their nerves and expansion of their vessels, fully illustrates this theory of animal heat, and particularly with reference to inflammation.

15. *d. Swelling* has been assigned above as one of the changes constituting inflammation. But, from what I have already stated, it should be viewed rather as a consequence of this act, than as an essential part of it. Besides, swelling is not always present, owing to circumstances about to be noticed. The morbid state of the organic nerves and the expansion of the capillaries are the earliest causes of swelling. But, as the diseased action proceeds, a more or less copious exudation of serum into the areolar tissue takes place; a portion of the serum and even of the red particles of the blood passes through the pores or distended walls of the capillary canals, especially in cellular or mucous tissues, distending, tumifying, and thickening the inflamed part. Hence the areolæ of cellular structures are found filled with a serous, sero-albuminous, and often with a sanguineous fluid, in which flocculi are sometimes seen floating, or adhering to the parietes of the areolæ or cells; these parietes being often thickened.

16. The *nature* of the swelling entirely depends upon the state or kind of fluid thus exuded from the inflamed capillaries.—The *state* of the fluid depends upon the kind of disorder of the organic nervous influence of the part, and of the constitution generally, and upon the degree of vital power exerted by the system. — In the *sthenic species* of inflammation, this power, however much it may deviate from the healthy condition, is at least not depressed below this condition. The fluid exuded is therefore a product of increased or sthenic vascular action, excited and kept up by the influence exerted on the capillaries by the nerves in which the disorder originated. Hence it is generally sero-albuminous, or a mixture of serum and coagulating lymph, sometimes containing colouring particles when the morbid action is intense; and the consequent swelling is firm, tense, and limited as to extent. The sero-albuminous or coagulating character of the effused fluid entirely depends upon the sthenic nature of the inflammation, and is of the utmost importance as respects the subsequent changes. When the organic nervous or vital power, locally or generally, is depressed, or otherwise vitiated as well as depressed, the effused fluid is not albuminous, and does not coagulate. It is then either serous, or sanguineous, or even sanious; and does not possess the characters of coagulable lymph. The consequent swelling is œdematous, soft, diffusive, or spreading, owing to the fluid state of the exudation, and its more ready infiltration into the surrounding parts. Whilst organic nervous or vital power is unreduced, the exuded matter occasioning the swelling in the advanced stage of inflammation, at least partially coagulates, and limits the extension of tumefaction. But when this power is much reduced, or greatly vitiated, as in the different forms of *asthenic* inflammation, this matter retains its fluidity, infiltrating and infecting the surrounding tissues.

17. The existence and amount of swelling chiefly depends upon the nature of the inflamed tissue. It is neither so early nor so obviously present in inflammation of dense structures, as in

that of soft and yielding parts. It is inconsiderable in fibrous, fibro-cartilaginous, and serous tissues, and is hardly apparent until the morbid action has continued for some time. In cellular, mucous, and parenchymatous tissues, the swelling is early and considerable. In certain parts, as in cellular tissue bound down by aponeurotic expansions, and in the internal structure of organs surrounded by fibrous or unyielding membranes, the swelling is less, or more slowly developed; the pressure thus occasioned restraining the effusion and the expansion of the capillaries. But, where the morbid action is intense, the pressure gives rise to a most distressing sense of tension, interrupts the functions of the organ, and sometimes even the circulation in it, thereby destroying its vitality and occasioning dissolution. When the substance of the brain is inflamed, the nature of its circulation, the great division and tenuity of its capillaries, and the unyielding nature of its surrounding structures, combine to prevent it from becoming much swollen. Yet there is every reason to believe that more or less swelling actually occurs (see art. APOPLEXY, and BRAIN —*Inflammation of*), and that the pressure on the inflamed organ, occasioned by the unyielding parts surrounding it, gives rise to the more dangerous symptoms observed in the advanced progress of the disease.

18. *e.* The *functions* of an inflamed organ, tissue, or part, are, as Mr. MORGAN has very justly contended, more or less disordered; and I may add, that the disorder is one of the earliest phenomena or constituents of the morbid action, being nearly coëtaneous with the change in the organic nervous power, on which this action depends. The disturbance of the functions is generally in proportion to the violence of the disease. If the inflamed part performs a secreting function, the secretion is either diminished, increased, or altered in character. — *Diminution* of this function is observed, when the cutaneous surface is inflamed, at the commencement of acute inflammation of serous and mucous membranes, and when the morbid action in glandular secreting organs is sudden or intense. When parts near the surface are inflamed, perspiration is obstructed, and the temperature is thereby increased. It is only at the commencement of inflammatory action in serous and mucous surfaces, that their secretions are diminished: as the disease proceeds, their secretions become increased, but at the same time changed in their characters; the change varying with the intensity, form, and duration of morbid action, and with the state of the patient. Inflammation of glandular organs is generally attended by suspension or diminution of their secretions, as in hepatitis, nephritis, &c. But in many cases, one kidney only, or a portion of the liver, may be inflamed, the secretion being only diminished or somewhat altered. It should, however, be recollected, that the secretions of an organ may be suspended, increased, or morbidly affected, otherwise than by inflammatory action.

19. The lesion of function attending the commencement of inflammation obviously depends upon the primary affection of the organic nerves. That accompanying the advanced progress of the morbid action proceeds not only from this source, but also from the alteration in the capillary circulation, from the consequent effusion of lymph in the inflamed tissue, and from the swelling and mechanical obstruction thereby produced.

20. The *throbbing* is connected with the obstruction to the return of blood, particularly from the expanded capillaries, into the veins. It is synchronous with the pulse, and is caused by the injection of blood into the part on each contraction of the left ventricle of the heart. It increases and renders the pain pulsatile; when it occurs at an advanced stage of inflammation, it is usually soon followed by suppuration. It is increased by a depending position of the inflamed part, and by whatever either obstructs the return of blood from, or favours the flow of it to, the seat of disease.

21. *B.* OF THE LOCAL APPEARANCES AFTER DEATH. — Certain of the preceding local characters of inflammation necessarily disappear with the termination of life; and the rest, as redness and swelling, either vanish, or remain for some time afterwards.—*Redness* does not always continue after death; its absence, therefore, is no proof that inflammation had not existed during life. Its presence also, *post mortem*, is not sufficient evidence of its dependence upon this cause. At an early stage of inflammation, and before the capillaries have lost their vital tone or contractility, and before much serum or lymph has been effused, redness generally disappears after death. Even when much effusion of fluid, and other changes consequent upon the morbid vascular action, have taken place, the blood may have entirely forsaken the vessels before the parts have been examined. Where redness actually exists, much discrimination is necessary to determine, whether or not it has proceeded from inflammation, or from a dependent position, or from transudation of the colouring matter of the blood from the vessels, or from incipient decomposition. It may arise from either of these. In many cases, two or more combine to produce it: a depending position favours both the gravitation of the fluids in the vessels, and the exudation of the colouring particles in the lower parts. The injection caused by position more readily occurs in parts which have been inflamed, than in those previously sound. Much, however, depends upon the seat and form of inflammation, and upon the circumstances connected with dissolution. Next to position, obstructed circulation through the heart or lungs, or obstruction to the return of blood in the veins, most frequently occasions non-inflammatory injection and redness, particularly in mucous surfaces; but, in such instances, the redness is more or less general or diffused in these parts, or exists in situations remote from each other, and is not attended by the usual products of inflammation. Attention to the circumstances causing redness of parts after death will generally enable the practitioner to infer with accuracy its dependence upon inflammation. When it is associated with any of the usual products or consequences of this disease, as the effusion of lymph, or of a sero-albuminous fluid, with softening, swelling, &c., then no doubt as to its origin need be entertained. (See *Diagnosis.*)

22. *C.* OF THE CONSTITUTIONAL SYMPTOMS OR EFFECTS OF STHENIC INFLAMMATION. — The constitutional phenomena vary remarkably with the exciting causes, the intensity, and the seat of inflammation; and they are further modified by age, habit of body, diathesis, and epidemic constitution.—When inflammatory action takes place in

a previously healthy person, and from causes which do not materially vitiate or depress the vital powers, or contaminate the circulating fluids, the constitutional effect presents certain features which are rarely wanting. It has been variously denominated, as *Symptomatic Inflammatory Fever*; —*Sympathetic Synocha*;—*General vascular Reaction*; — *Inflammatory Fever*, &c.; and has been improperly described in connection with, or rather as a species of, true fever. Indeed, some writers, as I have shown in the article FEVER (§ 91.), particularly CLUTTERBUCK, MARCUS, and BROUSSAIS, have contended that the *constitutional affection*, produced by the local changes constituting inflammation, is in no respects different from *idiopathic fever*. In the article just referred to, I have stated sufficient to prove the very remarkable differences between the two (§ 26—30.); and I shall hereafter succinctly notice the subject. Indeed, the former is altogether distinct from the latter, and should not be considered in connection with it, further than to point out the diagnosis.

23. In some constitutions, particularly the sanguineous, the irritable, and the nervous, the local lesions described above (§ 6.), very soon after their commencement, create more or less constitutional disturbance and febrile commotion; whilst in others, as the phlegmatic or lymphatic, the melancholic or bilious, these lesions may have been of some continuance, or have proceeded far, before general disorder is developed, or becomes severe. The local change being the same, the constitutional effect will vary remarkably in grade, form, and course, according to these and other circumstances just mentioned. In some, it will be rapidly developed; in others, slowly, or after a precursory period of longer or shorter duration, or after several efforts to produce it. The earlier constitutional symptoms are often neglected by the patient, and are seldom subjected to the physician. Occasionally the patient experiences chills or rigors more or less severe, almost immediately after sensations of pain or uneasiness. In rarer cases, morbid sensation is not produced, until either during, or after, the rigors. This is observed most frequently in inflammations of internal organs. More commonly the patient complains, in connection with pain, of uneasiness, or other morbid states of sensation referrible to a particular part, of weakness of the limbs, lassitude, general uneasiness, or lowness of spirits, of slight chills, formication, or of an alternation of slight chills and flushings. These may be the only precursors; or they may be attended by disturbed sleep, a whitish or loaded tongue, a clammy state of the mouth, with vitiated taste, want of appetite, constipation, &c. With these, the local symptoms are aggravated, and severe rigors or shudderings are more or less rapidly produced. The rigors are sometimes accompanied with nausea or vomiting. The countenance, general surface, and extremities, which were pale, harsh, or cold, during the rigors and chills, soon afterwards become warm; and the pulse, which was previously small or constricted, and but little accelerated, increases in quickness and volume. The consequent phenomena appear with a rapidity and severity, varying with the intensity and extent of the local action. The secretions and excretions are diminished, and subsequently vitiated. The skin is hot and burning, the face flushed; the tongue is white, furred, or loaded, and, with the mouth, somewhat dry or clammy; the appetite is gone; thirst is urgent; the bowels are constipated; the urine is scanty, high-coloured, clear, and emits a strong odour; and pains are often felt in the back, or loins, limbs, or head, in addition to those referred to the inflamed organ. The symptoms indicate general vascular excitement and its usual consequences, unconnected with depression of vital power, or contamination of the fluids. When they are severe or intense, and when the energies of life become exhausted, delirium sometimes takes place, particularly at night; but it rarely appears early, unless the brain is the seat of inflammation, or readily sympathises with the local affection, as in inflammation of the diaphragm or of fibrinous parts.

24. The acuteness of the general symptoms is not always in relation to the severity of the local changes; but, according to the intensity of either, or of both, will the type of the former be more manifestly continued. The less severe states of constitutional affection, and particularly when the local morbid action is neither extensive nor very acute, are characterised by exacerbations in the evening or night, during which the local symptoms are more or less exasperated; restlessness and want of sleep being generally present. In the morning the symptoms are ameliorated, and a tendency to perspiration appears. The course and duration of the constitutional affection vary with the severity and the seat of the local disease, and with the circumstances proper to the individual affected. The symptoms usually increase either gradually or rapidly, according to the nature of the exciting causes, the acuteness of the attack, and the circumstances just alluded to, until they arrive at a certain pitch or *acmé*, from which they decline more or less rapidly in some cases, and slowly in others. This change, whether taking place gradually and slowly, or suddenly and rapidly, depends entirely upon the state of the local affection. If the local symptoms gradually decline, the general disturbance subsides in a similar manner; and if any of the more unfavourable terminations of the local disease about to be noticed occurs, the system evinces the change, as will be hereafter stated.

25. *D.* OF THE CHANGES OBSERVED IN THE BLOOD IN STHENIC INFLAMMATION.— These vary remarkably with the circumstances determining the severity, seat, and course of the disease. I have described them so fully in the article BLOOD (§ 96. *et seq.*), that little more need be here adduced upon the subject.—Much importance has been attached to the existence of a *buffy coat*, and of a *cupped* appearance of the coagulum. These states of the blood are most frequently observed in the species of inflammation now being considered. But they are not always, nor even very generally, present, nor at all stages of the disease in which they occur. They are even more commonly met with in some complaints which, although nearly allied to inflammation, are not purely inflammatory, as rheumatism. They have frequently a marked reference to the stage and seat of inflammation. In acute rheumatism they are very remarkable, and often become more so as depletions are repeated. I once witnessed a case of the internal metastasis of rheumatism, for which venæsection was repeated several times. The buffed and cupped appearances became more and more remarkable; and yet, upon examination after death,

no signs of inflammation could be detected, and the internal viscera were quite bloodless. When, however, serous and fibrous structures are inflamed, these states of the coagulum very generally exist. During acute inflammation of cellular and mucous tissues, they are much less frequently observed. When compound or parenchymatous structures are inflamed, they are met with chiefly in certain stages and states of the disease. When an important or vital organ is inflamed, and especially when the patient is plethoric, and the circulation oppressed, these appearances often do not take place until the vascular load and oppression are removed, and the circulation is rendered free. There are various other circumstances which affect the state of the coagulum in acute sthenic inflammations, but they are noticed in the article just referred to. It is chiefly in the venous blood that *cupped* and *buffed* appearances have been seen; for the occasions of noticing them in arterial blood are comparatively rare and unfavourable to their occurrence. They have, however, been met with in arterial blood by GORDON, GENDRIN, and others.

26. *The coagulation of the blood*, and the origin of the buffy coat of the coagulum, have been so fully considered elsewhere (see art. BLOOD, and my *Appendix* to RICHERAND's *Elements of Physiology*, p. 638.), that I need adduce but little further on the subject, than to state the facts ascertained, and the inferences deduced, from my investigations, and published in 1824, in the first edition of the *Appendix* just mentioned. — The blood during life consists of serum, holding in suspension small regular and insoluble globules, each of which is composed of a central colourless spheroid corpuscle, and a coloured envelope. The latter always continues to surround the former during life; but, as life departs, and as the motion to which it gives rise ceases, the attraction between the central corpuscles and their coloured envelopes no longer exists, the one completely separating from the other. The central corpuscles then obey the force which tends to unite them, and form a network in whose meshes the liberated colouring matter, now detached from these corpuscles, becomes inclosed, and thus the coagulum is formed. These central corpuscles, in uniting into filaments, or other forms, constitute the fibrine, which, as respects its constitution, is probably only a modified or more highly animalised albumen, which abounds more or less in the serum. When the coagulum of the blood is exposed to a stream of water, the colouring matter, detached from the central corpuscles, is washed away, whilst the corpuscles themselves remain aggregated in the form of fibrinous filaments. It is the various forms assumed by the aggregation or mutual attraction of the central corpuscles, in relation to the separation, deposition, or entanglement of the colouring matter, and to the appearances of the serum in which these changes take place, which constitute the phenomena of coagulation, and give rise to the appearances of the blood characteristic of inflammatory action. In addition to these facts, the following *inferences*, as to the causes of the phenomena of coagulation, may be abridged from my notes above referred to: —

27. 1. The globules of the blood possess a rotatory motion during life, this motion continuing until shortly before coagulation takes place. — 2. This motion is the consequence chiefly of the organic nervous or vital influence which is exerted by the ganglionic system on the heart and blood-vessels, and which is partially imparted to the globules. — 3. This influence thus preserves the blood in a state of due fluidity. — 4. The fluidity of the blood is hence a vital phenomenon, or property *derived* from, and depending upon, the vital conditions of the vessels in which, and the organs through which, it circulates; the vital conditions of the vessels and organs depending, as shown elsewhere, chiefly upon the organic nervous influence. — 5. The cause of the *coagulation* of the blood is not to be found in external agencies, but in the loss of the vital influence and motion of the globules, proceeding from the sources just assigned — the power exerted by the ganglionic upon the vascular system. — 6. The presence of air, particularly the oxygenous portion of it, and several physical and chemical agents, hasten coagulation, whilst others delay or altogether prevent it. — 7. When coagulation commences at any point of a mass of blood, it is rapidly propagated throughout the whole: rest favouring coagulation; whilst motion delays or prevents it. — 8. The heat of the body and the strength of the circulation are not causes of the blood's fluidity, but are both results of the same cause, namely, the vital energy of the vessels, and vital endowment of the globules of the blood: both are co-ordinate; and both, as well as the phenomena connected with coagulation, are dependent on this source. — 9. Coagulation occurs sooner in venous than in arterial blood; and coagulation of arterial blood is still longer delayed if it be prevented from leaving the arteries. — 10. Coagulation takes place the sooner after the blood is removed from the vital sphere of the system, the weaker the vital energy to which it was subjected whilst circulating in the system. — 11. The weaker the vital energy, and consequently, the quicker the coagulation, the more lax is the coagulum which is formed. — 12. Coagulation is more slow, and the coagulum more firm, the more energetic the vital action of the vessels. — 13. As the central corpuscles lose their coloured envelopes soon after their removal beyond the sphere of the vital influence of the vessels, and as this is the first part of the act of coagulation following the loss of motion of the globules, so it may be inferred, that the colouring matter continues to surround the central corpuscles in consequence of the vitality emanating from the interior of the vessels and endowing the globules; and that the separation of the colouring envelope from the central corpuscle is the result of the loss of a portion or of the whole of that vitality, and of the rotatory (1.) motion which it occasions; and, as the loss of vitality may be reasonably supposed to be quickest where it has existed in the lowest grade, the separation of the coloured envelopes, and the attraction of the central corpuscles forming the fibrine, will be the quicker, the weaker the vital energy, and *vice versâ;* but the coagulum will be the more lax or imperfect, as shown by the facts already stated (10, 11.). — 14. Although the loss of the rotatory motion and of the colouring envelopes of the globules disposes the central corpuscles to attract each other, yet the attraction is weak in proportion to the depression of organic nervous or vital power endowing the vascular system at the time when the blood is abstracted; and in some inflamma-

tions, as well as in some other diseases, the depression may be so extreme as to deprive the central corpuscles of all power of uniting in the form of fibrinous filaments. In such cases, these corpuscles merely mix with the serum like a gelatinous or albuminous matter, and either suspend the colouring substance, or allow its deposition to the bottom of the vessel; the central corpuscles separating imperfectly from the serum or combining with its albumen, or forming merely an almost colourless gelatinous mass in the upper parts of the coagulum. — 15. The firmness of the coagulum is in proportion to the degree of organic nervous influence endowing the vascular system, and to the emanation which the globules themselves derive from this influence.

28. From what is now advanced, the appearances of the blood in inflammatory and other diseases will be readily explained. When the organic nervous power is depressed or exhausted — as in asthenic inflammations, in typhoid and adynamic fevers, in the true infectious puerperal fever, and puerperal mania, in the worst forms of erysipelas and diffusive inflammation of the cellular structures, and in several other diseases, particularly when epidemic, or occurring in hospitals, the air of which is vitiated by crowding of the sick, and the decomposition of the discharges and secretions, as in lying-in hospitals — the blood taken from a vein will often not separate into a distinct coagulum and serous fluid, but will assume the appearance either of a black, grumous, sanious, semi-gelatinous mass, or of a straw-coloured jelly, at the bottom of which jelly the colouring matter forms a loose reddish brown, or blackish, stratum. In such cases, the blood, participating in the deficiency of the vital energy of the body, and being also, perhaps, deranged from the admixture of hurtful materials with it, which are not duly eliminated by the various emunctories, evinces the lowest grades of vital endowment — the attraction between the central corpuscles of the globules being too weak to form a coagulum and to exclude the serum, the colouring envelopes separating speedily from the central corpuscles, and forming a loose stratum at the bottom of the vessel.

29. It may be inferred, as corollaries from the foregoing, that the appearances which the blood exhibits have always an intimate relation to the vital conditions of the system, and to the excitement of the heart and blood-vessels; that the buffy coat is merely one of the manifestations furnished by the blood, indicating reaction of the powers of life, or excitement of the vascular system; that the blood participates in the vitality of the body, through the medium of the vessels and organs in which it circulates; and that, according to the degree or condition of this vital endowment, coagulation and the coagulum are modified in their phenomena and appearances, and the production of the buffy coat promoted or altogether prevented. (See art. BLOOD, § 81. *et seq.*)

30. ii. OF CHRONIC INFLAMMATION. — Inflammation may affect any tissue or organ in so mild and obscure a form from the commencement, as to proceed for a long and indeterminate period; and, in many cases, to escape detection for a long time, owing to the slightness and gradual progress of the phenomena constituting the inflammatory act. This may be termed *Primary Chronic Inflammation.* The chronic form of inflammatory action is, however, frequently observed to follow the acute disease; the latter, owing to diathesis, treatment, premature exposure, and to the operation of injurious agents before recovery had taken place, only partially disappearing, or degenerating into a milder and more prolonged state of action. This state may be called *Consecutive Chronic Inflammation.*

31. *A.* The *Local Symptoms* vary remarkably with the mildness or severity of the morbid action; for, as the term *chronic*, as well as *acute*, is merely conventional or relative, both marking extremes of action, between which every intermediate grade is to be found, each of the phenomena already described, as characterising sthenic inflammatory action, appears in different states of development in different cases and circumstances. Generally speaking, however, all the local symptoms are much less severe than in the acute disease, and sometimes so slight as to escape detection. — *Pain* is occasionally absent, or is so slight as not to excite attention. — *Redness* is also sometimes slight, or not very remarkable. — The *temperature* is not much elevated: it is often not above the natural standard. — *Swelling* is frequently slight, but it is sometimes very considerable; and throbbing is seldom complained of. — The *functions* of the organ, or part affected, are generally more or less disordered; but in some instances the disorder is slight, or even escapes detection. This is especially the case when a portion only of an organ or part is chronically inflamed. When an internal organ is thus affected, it is chiefly by the presence of disordered function, and by the constitutional or sympathetic effects of the morbid action, that the nature and seat of the disease can be detected.

32. *B.* The *Constitutional Symptoms* are often slight and obscure, — sometimes prominent and characteristic. — *Febrile symptoms* are not always present; and even when most manifest, they are rarely of a continued type. They are generally remittent, or almost intermittent; the exacerbations being preceded by languor, uneasiness, or slight chills, followed by increased frequency of the pulse, by thirst, dryness of the mouth, and heat of skin. These symptoms come on in the evening, impair the rest, and subside in the morning, either with or without perspiration. The general health is more and more impaired, the strength fails, the flesh wastes, and the complexion waxes pale, sallow, or unhealthy. If the generative or urinary organs are the seat of the disease, various nervous or sympathetic symptoms are present; and if matter forms, or ulceration takes place, the chills become more severe, the febrile exacerbations terminate in copious perspirations; the urine is thick after standing, or deposits a sediment; emaciation proceeds more rapidly, and hectic fever is established.

33. iii. PROGRESS AND DURATION.—The progress and duration of sthenic inflammation are influenced by the constitution or diathesis, habits of life, age, and sex, of the patient; by the structure or organ affected; and by the treatment and influences to which the disease is subjected. The sanguine and irritable temperaments, a full and robust habit of body, and youth or the vigour of age, not only impart a sthenic character to inflammation, but also cause it to assume an acute or active form, or to run its course rapidly. A

similar effect is favoured by parts which are naturally vascular, and supplied abundantly with nerves, or endowed with high sensibility, and especially if they be placed near the centre of the circulation. On the other hand, the melancholic leucophlegmatic, and nervous temperaments, the scrofulous diathesis, an advanced period of life, and the female sex, prolong the progress of inflammatory action, and cause it to assume, either primarily or consecutively, a latent, languid, or mild and chronic, form. Structures endowed with little vascularity, and with a low grade of sensibility, as tendons, ligaments, fasciæ, and bones; also parts far removed from the centre of vitality and of circulation, as the extremities, are most prone to inflammation of a slow and chronic character.

34. The patient's habits of life have a remarkable influence in determining the character of inflammation from the commencement, — in favouring the passage of the acute into chronic disease, and in disposing the latter to assume the former state. Full living, and the use of much animal food, or of exciting and intoxicating liquors, have these effects especially, and not only prolong or aggravate the morbid action, but also cause its unfavourable termination. Similar results are also produced by injudicious treatment; by exposure to a close, miasmatous, foul, or unhealthy atmosphere; by certain epidemic constitutions of the air, depending upon electrical conditions, or other circumstances; by mental anxieties and perturbations, and improper or premature exercise or excitement of the functions of the part affected. These not only prolong or aggravate acute inflammation, but also render its terminations more unfavourable than they otherwise would have been; and cause slight or chronic inflammatory action to pass into the acute and active state.

35. The circumstances just alluded to render the *duration* of sthenic inflammations quite indeterminate. The active and acute states may continue but a short period, — but two or three days, or even not so long, until one or other of the terminations about to be described takes place; and the slight or chronic state may endure months, or even years. Between these extremes, every intermediate term of duration, as well as grade of action, may be seen. The duration depends chiefly upon the organ affected; acute inflammation in vital parts, especially the stomach and bowels, terminating most rapidly.

36. iv. The Complications of sthenic inflammations deserve some notice, although hitherto the subject has received no attention from pathological and practical writers, owing manifestly to the "*verba magistri*," the dictum of Hunter, — that two diseases cannot co-exist in the same frame. This, however, does not apply to inflammations, and hardly to other diseases, not excepting even specific contagions. The one morbid action may mask or absorb the other; but the one that predominates has its principal features somewhat modified by the association. In cases of chronic inflammation, particularly in females, and in young or nervous subjects, the sympathetic disturbance produced by it, will often attract the chief attention of the patient, and also of the physician; and a disease, truly depending upon inflammatory action, in some one of its grades, may be viewed as nervous, spasmodic, or functional. This most frequently applies to inflammations of the uterine and urinary organs, of the cerebro-spinal masses, and of the digestive mucous surface; and is fully illustrated in the articles Hysteria, Hypochondriasis, &c.

37. When a vital organ is inflamed, either acutely or chronically, other parts sympathise more or less; and when the inflammatory action is slight, the affected organ may not manifest the disorder by characteristic phenomena, the sympathising parts actually presenting the chief disturbance. Parts, also, which were at first only sympathetically affected in their functions or sensibility, may either, from the severity, or from the continuance, of such affection, become more and more seriously diseased, until the structure is changed; and thus, what was merely a symptom, increases to a morbid association; and, lastly, to a true complication; or even, ultimately, becomes the principal disease, the primary inflammation subsiding, or entirely disappearing, as the consecutive complication is developed. Instances of this are not infrequent in respect of inflammations of the lungs, pleura, pericardium, and heart; the disease originating in either, and extending to the others; the primary affection being masked by the consecutive disorder, and sometimes ultimately absorbed by it. Such occurrences still more frequently take place when any one of the abdominal viscera is inflamed; two or more of them becoming consecutively affected, the disease either continuing for a time to co-exist in them, or disappearing from the one as it is developed in the others.

38. The complication of inflammations with each other, or with nervous, spasmodic, or convulsive disorders, or even with hæmorrhage, is much more common than is usually supposed, — the latter often depending upon the former, particularly when the inflammation is chronic, slight, or latent. In such cases, the passage of the disease into a more acute or active form becomes an advantage, by disclosing its nature. Such complications are frequent in childhood, and in females, particularly during the puerperal states. Many of the convulsive affections of the former derive their origin, in a large proportion of cases, from inflammatory action; and most of the nervous, spasmodic, painful, and hysterical disorders of the latter, arise from inflammatory action of a slight and chronic form in the uterus, ovaria, or urinary organs.

39. v. Terminations and Consequences.—Inflammation, correctly speaking, terminates only in *two* ways: in *resolution*, or the recovery of the healthy state of action; and in *gangrene*, or the death of the inflamed part. The other morbid conditions, improperly ranked as terminations, are merely *consequences* of inflammation, the morbid vascular action giving rise to them, still subsisting in most instances, in some one or other of its forms. — *A.* When inflammatory action terminates in *resolution*, the phenomena subside very nearly in the order in which they appeared. Pain ceases; the redness and heat diminish; the swelling subsides gradually, and the functions slowly return. In many cases, however, the swelling continues with little diminution for a considerable time, and the functions of the part are restored with equal slowness; the recovery of the impaired tone of the capillary vessels, and the absorption of the sero-albuminous fluid effused in the areolæ of the tissues, being

necessary to the subsidence of the swelling, and to the restoration of function. This termination may be looked for when the inflammation does not proceed too rapidly; when the pains are neither acute, lancinating, nor throbbing; when the symptomatic fever gives rise to a general and copious perspiration; and when the urine deposits a sediment.—*B*. The termination of inflammation in *gangrene*, is so fully discussed in that article, that nothing further need be advanced respecting it at this place. (See art. GANGRENE, § 3. *et seq.*)

40. *C*. Of the *consequences* or *results* of inflammation, the most important are —*exudation*, *softening*, *suppuration*, *ulceration*, *induration*, *thickening*, and, probably, other organic changes. Several of these are treated of in separate articles; a simple reference to which, at this place, will be sufficient. — *a*. *Exudation* or *effusion* is the earliest and most common consequence of inflammatory action; the swelling, constituting one of the chief characters of inflammation, being caused by it chiefly. Exudation is the deposition, in the areolar tissue, in the parenchyma of an organ, in a cavity, or upon some surface, in consequence of excited vascular action, of a fluid consisting chiefly of the natural secretion of the part, greatly increased in quantity, and remarkably altered in its properties and appearances. This exudation sometimes commences at a comparatively early stage; but most commonly it becomes abundant at an advanced period, or even towards the close, of the morbid action; and it occasionally favours a resolution of this action, but not infrequently some degree of inflammation still subsists with it. The fluid which is exuded or effused, varies in its characters with the structure affected, and with the degree or activity of the morbid action producing it. Something also depends upon the function of absorption in the part; for when it is active, and the more fluid parts of the exudation are thus removed, the state of the remaining parts will be thereby much modified. Hence the fluid is serous, sero-albuminous, flocculent, turbid, liquid, thick or partially consistent, ropy or glairy, coagulated, adherent, albuminous, or even membranous or fibrinous.— The fluid exuded in inflamed cellular or parenchymatous structures is generally serous, turbid, sero-albuminous, or flocculent, but becoming more consistent, albuminous, or otherwise changed, as absorption proceeds. That which is exuded from inflamed serous surfaces is either fluid and transparent, or turbid and flocculent, or thick, semi-coagulated, and albuminous; films or layers of lymph, or of albuminous matter, covering the affected surface, or agglutinating opposite parts. The fluid exuded from mucous surfaces varies in different situations, and as the follicles, or the mucous membrane itself is principally affected. Hence the morbid secretion is watery or thin; or mucous, thick, and opaque; or glairy, ropy, gelatinous, and transparent; or muco-puriform, or sanguineous; or muco-albuminous, or consisting chiefly of an albuminous lymph.

41. The intensity or activity of inflammatory action influences, not only the quantity, but also the nature, of the effused fluid. When this action is weak or slight, the fluid is chiefly serous; and in proportion as it is more active or severe, the effusion is more albuminous, and presents the characters of coagulable lymph. But the effused fluid is also much modified by the constitution, diathesis, and habit of body of the patient, and by the vital and physical influences to which it is exposed for a time after its effusion. When the fluid is retained for some time in contact with surfaces which exuded it, the more watery portion is absorbed, and the albuminous part, or the lymph, becomes more plastic and solid, and, ultimately, even organised. This is shown especially in chronic and sub-acute inflammations of serous membranes. Even in mucous surfaces, as in the fauces, larynx, and trachea, the albuminous fluid exuded during inflammation is changed, not only by a partial absorption, but also by the evaporation, during the constant passage of the air over the parts during respiration. The scrofulous, the gouty, and the rheumatic diatheses further affect the quality of the fluids effused from inflamed surfaces; but still more depends upon the intensity of the general vascular disturbance, in connection with the state of vital power. When the former is energetic, and the latter unimpaired, then the effused fluid is albuminous, and abounds in coagulable lymph, a *formative*, as well as a *reparative*, process, frequently resulting therefrom; a formative process often appearing from inflammation of serous membranes, and a reparative process after the division or wounds of parts. When the febrile and vascular disturbance is great, and organic nervous or vital power is much impaired, the fluid effused is watery, sanious, turbid, septic, offensive, &c.; the morbid action being incapable of effusing a fluid sufficiently coagulable to be the medium of adhesion between opposing surfaces, or to limit the spread of the morbid action to surrounding parts. Hence inflammation, in these circumstances, assumes the asthenic, spreading, and disorganising characters about to be considered. One of the chief and most important features of sthenic inflammation is its disposition to exude a fluid more or less coagulable, by which parts adhere and unite, and which even becomes organised, and arrests the extension of the inflammation, as well as limits the destruction or disorganisation of the parts in which it commenced.

42. Albuminous or coagulable matter exists in the fluids effused or exuded by sthenic inflammation in various proportions. In the more liquid effusion, it is in small quantity, and is separated from the serum which suspends it, or holds it in solution, by heat and by the mineral acids; but of the more solid or consistent exudation, it constitutes the principal part. Between these extremes it is found in every proportion. In puriform matter and pure pus, albumen exists in the form of minute corpuscles, or globulus, swimming in a turbid serous fluid. In this, as well as in the more fluid states in which albumen presents itself, it is incapable of organisation; but, in the more solid or plastic state, it often becomes organised, and is the bond of union between divided parts, when the powers of the constitution, and the condition of the circulating fluids, admit of its production. Salutary or reparative effects, from the effusion of coagulable lymph, are evinced also by its effusion around *abscesses*, by its agglutinating serous membranes, when morbid formations, ulceration, and purulent matter are about to perforate them; and by its obliterating arteries or veins, after ligatures, or in circumstances where dangerous hæmorrhage

would otherwise occur. (See ABSCESS, and ADHESIONS.)

43. *b. Softening* is a very general consequence of inflammation, and one of the earliest which attends it. Indeed, inflammatory action seldom continues long, particularly in an acute form, without impairing more or less the vital cohesion of the tissues affected. It often precedes suppuration, and it generally increases the disposition to effusion. It is most remarkable in mucous and cellular parts, and in parenchymatous organs, particularly the brain, lungs, liver, &c.— these becoming more friable as well as softer, than natural. But softening from this, as well as from other morbid conditions, is fully considered in the *article* devoted to the subject.

44. *c. Suppuration* is the natural result of inflammation, when it is allowed to attain a high degree of intensity, especially in cellular, parenchymatous, and mucous structures. — *Pus*, the product of the suppurative act, is apparently produced from the albuminous part of the blood, by an altered state of the vital condition of the capillaries. It is very difficult to show satisfactorily in what this alteration consists; but it probably is impaired tone, or deficient vital contractility, of the capillary vessels, the arterial branches supplying them being still more or less excited. Suppuration may be viewed as a true act of secretion; although pus, as it usually appears, is somewhat changed in the course of its production by absorption, by the vitality of the parts with which it remains in contact, by temperature, and by evaporation. The small whitish flocculent masses often found in the purulent matter, consist chiefly of a more concrete albumen secreted by the inflamed part. Although suppuration chiefly takes place in the structures mentioned above, yet it sometimes is seen in other parts, especially in the cavities of joints, and more rarely in serous surfaces. In these situations, particularly in serous membranes, it is generally a result of intense action in connection with deficient power.

45. Mr. HUNTER was the first who recognised with any degree of accuracy the changes which take place in the blood, and in the capillaries of an inflamed part, during suppuration, inasmuch as he considered that pus was a remove further from the nature of the blood, than the matter formed by adhesive inflammation, — than coagulable lymph; and M. GENDRIN is of the same opinion. The formation of pus in an inflamed surface or tissue takes place as follows, according to the observations of KALTENBRUNNER, GENDRIN, CARSWELL, and the author.—In the field of a microscope, the inflamed capillaries seem uniformly red, and the circulation in them is retarded or has ceased. Serum and coagulable lymph are effused in the areolæ of the tissue; and, if the inflammation is very intense, the exuded fluid is more or less coloured by the exudation of red globules or of blood. The whole of the inflamed part is quite opaque. As soon as suppuration commences, the red colour begins to disappear in various points, giving place to a yellowish granular-like matter in the capillaries, and connecting cellular tissue. In the centre of the inflamed tissue, several of the capillary vessels, which were obscured by the accumulated blood, re-appear, — some containing red, others yellowish grey, globules, which gradually become more distinct, increase in number and size, begin to move slowly, and, traversing the capillaries, arrive at the surface of the tissue, or at the edges of the solution of continuity, if this has occurred, in the form of globules of pus (CARSWELL.). GENDRIN states, that he has distinctly seen the globules of blood, after stagnating in the capillaries of the inflamed part, losing their colouring envelopes, becoming opaque, and assuming a greyish yellow colour, approaching to that of pus; and that he has traced them moving slowly in the capillaries, and, as they advanced to the suppurating surface, gradually acquiring all the characters of pus. The observations of KALTENBRUNNER agree with those of GENDRIN, as to the transformation of the blood-globules into the globules of pus, and as to this taking place *within* the capillaries; but they also seem to prove, what I have observed in several instances, that the red globules, or blood, exuded in an intense state of inflammation into the areolæ of the tissue, undergo a similar change to that which takes place within the capillaries, when the circulation becomes stagnant in them; and that pus may thus be formed *without*, as well as *within*, the capillaries of an inflamed part, the fluid portion of the secretion consisting of the serum of the blood. KALTENBRUNNER even supposes, that not only the blood of the inflamed tissue, but likewise a part of the tissue itself, is converted into pus-globules. But, I belive that this takes place only where suppuration is followed by *ulceration* (§ 48.), or where an ulcerated surface secretes a puriform fluid.

46. From these facts it is evident, that, in an inflamed part, certain changes precede the formation of pus: — 1st. A loss of the vital tone, or a change of vital action in the extreme capillaries; — 2d. A retardation or stagnation of the circulation, and partial coagulation of the blood in them; — 3d. A change of the blood-globules into pus-globules, and the discharge of the latter with a portion of serum on the suppurating surface; — 4th. A similar change of the globules of blood extravasated in the inflamed part, — these globules losing their colouring envelopes and becoming the globules of pus. As connected with the subject of suppuration, some notice might be taken of the presence of pus in the general circulation, or in situations remote from the seat of inflammation; but as this belongs rather to the translation and metastasis of inflammation—to consecutive inflammation, it will be considered hereafter.

47. *Pus*, or purulent matter, — the product of suppuration, — is a slightly unctuous fluid, of the consistence of thin cream, which it otherwise resembles. It is generally of a whitish or pale yellowish colour, and of a mawkish or sweetish taste. It is nearly inodorous when cold, but when heated, it emits a faint, sickly, and unpleasant odour. Under the microscope, it presents corpuscles or particles swimming in a serous fluid. These corpuscles resemble the central corpuscles of the globules of the blood, deprived of their colouring envelopes, and consist of a highly animalised albumen. The serous part of the secretion differs but little from the serum of the blood. In many situations, pus is mixed with the more natural secretions of the part; the latter being either altered in their characters, or increased in quantity. This is especially the case in acute inflammations of mucous surfaces; the fluid excreted consisting of pus and mucus in variable proportions. The

other relations of suppuration are fully considered in the article ABSCESS.

48. *d. Ulceration* is distinguished from suppuration chiefly in its being attended by a loss of substance — by a destruction of parts; and by a more or less abundant secretion of a puriform, ichorous, fœtid, sanious, and variously coloured fluid. It may immediately result from inflammation, or be consequent upon suppuration, or the formation of an abscess. It depends chiefly upon causes connected with the treatment of the part in the earlier stages of inflammation; upon the diathesis, habit of body, or existing constitutional vice, as scrofula, scurvy, syphilis; and upon the state of the digestive and excreting functions. Ulceration is always preceded by softening — by a loss of the vital cohesion of the tissue inflamed, at the surface or part most remote from the centre of circulation, or at the termination of the capillary vessels. Along with the softening there is also a more or less copious effusion or exudation of a serous fluid, in which the organic molecules, which have lost their vital cohesion, are liquefied or suspended. Hence the discharge is ichorous, offensive, sanious, or coloured. In the more rapid or phagedenic states of ulceration, and when the discharge is scanty, and in parts covering abscesses, very probably the organic molecules are absorbed nearly as fast as they lose that degree of vital attraction, necessary to their cohesion in the diseased surface. From this, the relation of ulceration to sphacelation and gangrene, particularly hospital gangrene, is apparent. (See art. GANGRENE.)

49. When an ulcerated part begins to return to a healthy state of action, the diseased secretion becomes more puriform or albuminous; and an attempt is made to restore the loss of structure by a process called *granulation*. The vessels of the ulcerated surface acquire a more sthenic action; the disposition in the tissues to lose their vital attraction or cohesion is arrested; and the secretion assumes at first a puriform, and afterwards an albumino-puriform, character; the albuminous or cocoagulable portion of the secretion coating the inflamed surface, protecting it, and ultimately becoming organised or partially identified with it. These changes in the ulcerated surface are evidently brought about by an improvement in the organic nervous influence of the part; and hence the success of a treatment, general and local, calculated to restore or to promote the energy of this influence, especially through the medium of the digestive and respiratory organs.

50. *e. Induration*, and *thickening* or *hypertrophy*, of structures, consequent upon inflammation, are discussed in the articles on these lesions. It is unnecessary to offer any further remark respecting them, than that they are generally consequences of chronic inflammation, and of acute or sub-acute inflammations which have passed into the chronic state. They may also be referred to the exudation, into the areolar tissue, of a sero-albuminous fluid, the more serous parts having been absorbed, and the albuminous parts organised, or assimilated to the structure including them. From this source other organic lesions may arise, according as the exuded matters undergo a more or less complete organisation, or according as they are retained in the state of merely minute amorphous masses disseminated in the areolæ of the structures, and are preserved from dissolution or change by the vitality of the surrounding parts. (See arts. INDURATION, and HYPERTROPHY; also DISEASE.)

51. II. VARIETIES OR MODIFICATIONS.—Having described inflammation, as occurring in a previously healthy constitution, or in its *sthenic form;* and having viewed this as the more usual and standard condition of the disease, whether appearing in the *acute*, *chronic*, or *intermediate* states; it becomes necessary to consider the *alterations or deflections from sthenic inflammatory action*, occasioned by the previous health, or the existing constitution, of the patient, and by the nature of the predisposing, the exciting, and the concurrent causes. Many of the lesions of vascular action arising from these sources are so different from the true sthenic condition now discussed, as to admit of doubts as to the propriety of viewing them as inflammations; yet they have intimate relations to the sthenic disease, inasmuch as they possess nearly the same local characters as it, and often in a very remarkable degree, — as they differ from it merely in kind, and often by slight shades only, — as they may be converted into it by a general and local restorative treatment, — and as the sthenic disease may be reduced to some one of these lesions by various depressing influences, or contaminating agents.

52. In the view just taken of sthenic inflammation, we have seen merely different *grades* of action; the disease being *acute*, or *chronic*, or some intermediate state usually called *sub-acute*, according to the degree of *severity* or of *activity* presented by the morbid action, relatively to the constitution and powers of the patient. Whilst the term *active* has been applied by many to the more acute states of sthenic inflammation, the word *passive* has been used as synonymous with the chronic conditions. To the former of these appellations, and to its application, little objection need be urged; but the latter is by no means applicable to any state of inflammation — neither to the chronic states of sthenic inflammation, nor to the *asthenic varieties* about to be considered.

53. With the increased local and general vascular action, constituting the states of inflammation above described, the constitutional powers are not much reduced or otherwise altered, nor are the depurating functions impaired, nor is the blood materially vitiated or deteriorated, in the early stages at least, or until the disease approaches an unfavourable termination. But in the varieties about to be noticed, the powers of life are much depressed or otherwise deranged from the commencement, the depurating or excreting functions are interrupted, the blood more or less altered, and the nervous sensibilities increased. Hence, vital resistance to the changes consequent upon increased susceptibility and diseased vascular action is greatly impaired, and disorganisation rapidly supervenes, and as speedily proceeds, unless arrested by the most efficient means. To these circumstances, however produced, are to be imputed those alterations, or deflections, from the sthenic or true form of inflammation, that frequently present themselves in practice, with characters varying with the cause and seat of the disease, and with the peculiarities of the patient. As the inflammations already described present no obvious loss of power in their earlier stages, or until their terminations, and are therefore justly termed *sthenic;* so those about to be considered

may be generally denominated *asthenic*, from the want of organic nervous energy, and the loss of vital resistance to the progress of disorganisation, which they usually present, unless controlled by judicious treatment. They have also been denominated *typhoid*, *venous*, *erythematic* and *erysipelatous;* but these are chiefly specific terms, the generic appellations, *spreading*, *diffusive*, *disorganising*, or *asthenic*, being more appropriate.

54. i. OF ASTHENIC INFLAMMATIONS.—*A. Of the Local Alterations, or Characters.*—*a. Uneasy sensation*, or *pain*, is the earliest, and sometimes the most remarkable, symptom, particularly when serous membranes or circulating vessels are affected. When the disease is caused by external injury, by the inoculation of morbid matters, as in punctures during dissection, the pain is often early and acutely felt, even in cellular parts, although no other change has yet appeared. In nervous, susceptible, and weakened persons, the pain is so acute as to accelerate or increase the restlessness or delirium consequent upon the constitutional symptoms, which are often remarkably severe, compared with the apparent small extent of the local disease, especially when caused by an animal poison. Pain, however, is frequently not very severe in certain forms of asthenic inflammation, particularly when parenchymatous organs are their seat, and when they are consequent upon some disease, which has lowered or exhausted organic nervous power and sensibility. The inflammations which complicate or appear in the course of continued fevers, are illustrations of this; and the metastasis of erysipelas, or the transference of inflammation from an external part to an internal organ, seldom gives rise to much pain. The amount of uneasy sensation depends chiefly upon the tissue implicated, upon the exciting cause, upon the constitutional susceptibility of the patient, and upon the state of the blood. In cellular, mucous, and yielding structures, it is sometimes slight, particularly if the purity of the blood is impaired by imperfect excretion, unless the inflamed and turgid parts be partially strangulated by aponeurotic expansions or other unyielding textures, as in diffusive inflammation of the *cellular tissue*, and in various states of *erysipelas*. In this latter, and in inflammation of the lymphatics, the pain is generally tensive, burning, or stinging, and occasionally remittent. There are always great tenderness, and sensibility to the touch, unless the affected parts are deeply seated.

55. *b. Redness* and *vascular injection* are always very remarkable. The former often either rapidly passes into a deep, dark, brownish-red, livid, or purplish hue; or presents more or less of either of these from the commencement. It is sometimes of a pale or yellowish red tint. The vessels are injected and distended, and the current of circulation through them is slow, or impeded. The already dark hue of the blood is further deepened by this congestion; and the exudation of the serous portion of it is facilitated by the weakened state of the vital cohesion of the tissues, by the impaired tone of the capillaries, by the increased frequency of the heart's contractions, and by the diminished crasis of the blood itself. The discolouration and injection of the part in the various asthenic states of inflammation are generally indices of the extent to which the vital tone of the vessels and tissues is exhausted, and the blood, especially that circulating in the part, is altered.

56. *c. Increased temperature* is present chiefly at the commencement of asthenic inflammation, and when membranous tissues and circulating vessels are attacked. Even in these cases, at an early period, the actual rise of temperature in the affected part is often not greater than on the surface of the body generally. Where the febrile disturbance is great, the pulse very quick, and the skin dry, the heat of the general surface and of the diseased part is very considerable; but it is also peculiar, as observed in typhoid and malignant fevers; it seems to be greater than it really is, and is attended by a stinging, harsh, and unpleasant sensation. As effusion into the areolar tissue of the part proceeds, and as the swelling extends, little or no increase of heat is usually observed; and sometimes the temperature of the part may even be lower than that of the surface of the trunk, or even lower than natural.

57. *d. Swelling* is considerable, and sometimes very great, when cellular or parenchymatous tissues are affected. It is caused at first by the relaxation of the vital tone of the capillaries and tissues, and by the injection of the former; but consecutively, and chiefly, by the effusion of serum from the diseased vessels. The swelling is always diffused, is disposed to extend itself, and is never acuminated or convex. It is generally soft, sometimes boggy or œdematous, and never elastic or hard, unless from the tension occasioned by aponeurotic or unyielding structures stretched over the swollen part. In mucous and serous membranes, it is much less manifest, although existing more or less; and, in them, it is owing chiefly to the distension of the capillary vessels, and to the relaxation of the tissues themselves.

58. *e.* The *secretions* and *functions* are always disordered by asthenic inflammation:—the former are altered and generally increased in quantity; the latter are remarkably impaired. When a secreting membrane or surface is attacked by it, the discharge is variously changed from the healthy state, the change obviously arising from the impaired state of vital power, the morbid condition of the blood, and the acceleration of the circulation. The effusion generally consists of a foul, dark, turbid, ichorous, septic, sometimes whey-like, fluid. In puerperal females, it is often remarkably abundant, and contains much curd-like or semi-coagulated matter, partially separated from a turbid or whey-like serum. This watery, serous, or ichorous fluid, is also abundantly effused in the areola of the asthenically inflamed cellular tissue (see *Diffusive Inflammation of* CELLULAR TISSUE); and, owing to the deficiency or absence of coagulable lymph or albumen, it readily spreads to, and infects, or contaminates, the surrounding tissues. This is one of the chief characters of asthenic inflammation; its *spreading* or *diffusive nature*, especially, resulting from the states of general or local vital power, and of vascular action, which are insufficient for the formation of coagulable lymph, by which the local disease may be limited.

59. The secretions from glandular organs are also remarkably altered in quality as well as in quantity; but their quantity is as often diminished as increased. Sometimes they are nearly or altogether suppressed, particularly in extreme cases

of the disease, manifestly owing to the loss of organic nervous influence or vital power, in connection with the distention of the capillaries. When the substance of the liver is the seat of asthenic or diffusive inflammation, bile is either not secreted, or is absorbed as soon as it is secreted, giving rise to one or other of the forms of JAUNDICE (§ 28.) described in that article as consequent thereon. The swelling, also, caused by the distention of the diseased vessels, and by the effusion into the parenchyma of the organ, is so great as to press upon the ramifications of the ducts, and to prevent the passage of the fluid along them as it is secreted. This is especially the case, when the secreting organ is inclosed in an envelope or membrane, which does not readily yield to the distension thus occasioned.

60. *B. The Constitutional Symptoms.* — Asthenic inflammations derive their peculiar characters, local as well as general, from either pre-existing disorder, or the poisonous nature of the exciting cause. The former consists chiefly of *debility*, as manifested in the assimulating, circulating, and excreting functions (see DEBILITY, § 12. *et seq.*). The vital powers are impaired throughout the frame, and especially in the organs of digestion, circulation, and depuration. Hence, with increased sensibility and susceptibility of the nervous system, the blood soon becomes affected, and is less suited for the production of a healthy secretion, and for the formation of coagulable lymph or albumen in the seat of inflammation, than in persons otherwise circumstanced. When asthenic inflammation depends upon the exciting causes, it will generally be found that they possess poisonous or contaminating properties which infect the frame, whilst they produce inflammatory action in certain structures by their specific operation, as in the infection of erysipelas; or which contaminate the system by acting directly upon the part with which they come in contact, as when a septic animal fluid, or an animal poison, is applied to a wounded or abraded surface. Very frequently asthenic inflammations derive their constitutional, as well as their local, peculiarities from both these sources, — from the previous state of health as well as from the nature of the exciting cause. In surgical practice, they not infrequently depend upon the severity of the shock sustained by the system, in cases of very severe local injury, as in extensive bruises and crushing wounds, or after operations. In all cases of asthenic inflammation, although the states of constitutional or vital power, and of the circulating fluid, are chiefly concerned in modifying the character of the local disease, yet the local, generally reacts upon the general affection, the one aggravating the other reciprocally and progressively, until either a fatal disorganisation, or arrest of function takes place, or a favourable change is brought about by energetic means. This is evinced especially in the diffusive visceral inflammations occurring in diseased or cachectic habits of body, or in the course of continued fevers, and in certain forms of erysipelas, and of inflammation of the cellular tissue.

61. The severity of the constitutional symptoms frequently has but little apparent relation to the extent of the local inflammation; the latter being comparatively slight, and presenting but little of the spreading, diffusive, or disorganising characters usually observed in connection with remarkable febrile commotion and vital depression. A person may experience a slight abrasion or puncture of the integuments, followed by inflammation to no great extent, with a more or loss foul discharge, or with a discharge not materially different from that following sthenic inflammation; and yet the constitutional affection may be of the most violent description, and characterised by excessive vascular action, by great excitement and morbid sensibility of the nervous system, and by remarkable depression of nervous power and of vital resistance. It is this state of disease especially which Mr. TRAVERS has so well described under the terms *Direct and Reflected Constitutional Irritation* — terms which, in the present state of our knowledge, convey as satisfactory an idea of the nature of these causes, as any other that can be employed. The remarkable constitutional disturbance characterising them, has been ascribed to sympathy; and probably it may be produced in some instances by the absorption of a morbid or poisonous secretion or fluid into the circulation. But the majority, and these the most severe and the most marked, as to all the peculiarities of these maladies, can be ascribed only to a morbid impression or lesion of the organic nervous system, that is soon propagated throughout the frame, implicating not only the vascular system, but also the cerebro-spinal functions, and all the vital manifestations. So intense a disease, produced by so slight a cause, and depending, apparently, upon so small a local lesion, is, it is true, very inadequately explained by the terms *irritative fever* and *constitutional irritation*, and far less by that of *constitutional sympathy*; but the difficulty is, to denominate them by any other name which shall be in every respect appropriate.

62. The constitutional symptoms attending upon asthenic, foul, or spreading inflammations, appear variously grouped or characterised; but they may be referred chiefly to the following types or varieties: — 1st. General and remarkable depression of organic nervous or vital power, without vascular reaction; — 2d. General depression of vital power, with vascular reaction or excitement; — 3d. Vital depression, with acute nervous sensibility and cerebral disorder; — and, 4th. Vital depression, with remarkable nervous excitement and vascular reaction. — Although the constitutional commotion usually appears in one or other of these forms, yet it must be admitted, that the arrangement is somewhat conventional; that there are often intermediate, or mixed, states of disturbance; and that the general affection may commence in either of these forms, and pass into another, owing to the influences to which the patient is subjected in its course. Nay, fever attending sthenic or adhesive inflammation may be converted into either of these low types of fever, by the more powerful depressing or contaminating influences; and the latter may be changed into the former, by agents of an opposite nature, — similar alterations taking place, from the same causes, in the characters, consequences, and terminations of the local affection.

63. *a. General vital depression, without reaction*, is not of frequent occurrence, and is produced only by a very sedative or poisonous cause, relatively to the power of vital resistance, when depending upon a slight local lesion. It is very

frequently observed after severe shocks, crushing injuries, and operations. However induced, it usually commences with a sense of general coldness, sinking, anxiety at the epigastrium, nausea, occasionally vomiting, and remarkable despondency or depression of spirits. The skin is of the natural or of a diminished temperature; and there is generally little or no thirst. The mental faculties become obscured or stupefied, and the countenance collapsed; and convulsive motions or twitches frequently occur. The pulse is weak, irregular, small, or compressible — sometimes quick or intermittent, but always deficient in power. Vomiting is often attended by little retching, matters being brought up with a species of singultus; and the alvine excretions are always morbid and offensive. As the powers of life sink, low delirium, coma, the supine posture, hiccup, complete physical prostration, sharpened features, and a cold clammy state of the surface, supervene; the local disease either becoming more deeply discoloured, or extending towards the centre of the body, or passing into gangrenous disorganisation.

64. *b. Vital depression, with general vascular excitement and reaction*, is much more common than the preceding variety of constitutional affection. It is generally ushered in by chills or rigors — sometimes with nausea and even vomiting. The skin soon becomes hot, dry, burning, or harsh; but occasionally the affected part is hot and burning, whilst the temperature of the surface is very little elevated. The pulse is generally above 110°, and sometimes it is 120°, or even upwards; it is compressible, open, broad, quick, and irritable — becoming more so, and smaller or weaker, as the disease proceeds. The tongue is foul or loaded, sometimes glossy, and afterwards dry and mahogany coloured. The evacuations are offensive, and otherwise disordered. Medicines, or substances taken into the stomach, are soon thrown off; and there is generally thirst, which is at first urgent, but becomes less so, and is at last not complained of, particularly when delirium takes place. Delirium first appears at night, and either remits in the morning, or continues; and is often followed by coma. In some instances, the vascular excitement is most rapidly developed, or reaction speedily follows the rigors, and all the symptoms soon become severe; violent headach, with anxious collapsed countenance, succeeded by delirium, appearing early. In other cases, the general excitement is more slowly and more moderately produced, and not until several rigors and attempts at reaction have taken place. In either case, exhaustion speedily occurs, and all the symptoms of the advanced stage of the preceding variety supervene. The disease is rapid in its progress, if it be not early arrested by treatment; and the local alteration extends more or less, assumes a more livid or dark hue, or more aggravated form, or becomes more disorganised. When pus has been formed at an early stage of the local affection, and is confined in deep-seated parts, or beneath fasciæ, it is often offensive, discoloured, and different from that discharged after sthenic inflammation. In many instances, the local alteration is apparently slight, in relation to the severity of the constitutional affection; but in others it has extended to a very considerable distance along the absorbents, veins, or cellular tissues, from its primary seat; and has thus either been overlooked, or has infected the blood. (See arts. CELLULAR TISSUE — *Diffusive Inflammation of;* ERYSIPELAS; LYMPHATICS, and VEINS.)

65. *c. Vital depression, with acute nervous sensibility and cerebral disorder*, is very often observed to accompany asthenic inflammations caused by animal poisons and septic animal secretions, especially by the inoculation of either of them during the dissection of dead bodies. In all these, the pain felt in the seat of injury is most excruciating, and is attended by general irritability and impatience; by irregular chills, loss of appetite, intense headach, white tongue, thirst, anxious countenance, nausea, and sometimes vomiting; a frequent, small, quick, or irritable pulse; hot and dry skin; sleeplessness followed by delirium; and, lastly, a dry brown state of the tongue; vomiting, singultus, coma, subsultus tendinum, collapsed features, cold clammy perspirations, and quick, laborious respiration. The febrile commotion often commences insidiously, and without rigors or chills, and proceeds with much rapidity. In this variety, particularly when produced by the causes just stated, morbid sensibility, general irritability, violent headach, and want of sleep, early delirium, and suppressed, imperfect, or weak vascular reaction, are characteristic phenomena; the other symptoms being less constant. The local alterations generally consist of early and remarkably intense pain; excessive and spreading tumefaction; and of purulent formations, first on the seat of injury, but extending successively to parts nearer to the centre of the body, until the trunk and large cavities are reached. The cellular tissue, in the course of veins and absorbents, or around the glands of the latter, is most commonly attacked; and, ultimately, the serous envelopes on internal organs, or even these organs themselves, occasionally become implicated; but other parts, particularly the lymphatics, fasciæ, and veins, are often also affected.

66. *d. Vital depression, excessive irritability, violent pain, and vascular excitement*, often attend cases of asthenic inflammation, arising from similar causes to those inducing either of the former varieties of constitutional commotion; the difference in the degree of vital depression in the one, of nervous disorder in the other, and of vascular excitement in a third, depending chiefly upon the temperament, habit of body, vital power, age, and previous health of the individual, and upon the nature of the exciting cause. In proportion as the cause is of a poisonous, depressing, septic, or contaminating nature, relatively to nervous susceptibility and vascular activity, will the local affection be diffusive, spreading, or disorganising, and the constitutional disturbance be characterised by a predominance of the symptoms marking excessive vital depression, or acute nervous suffering, or tumultuous vascular excitement, devoid of the power of resistance. When the impression of the cause, or the subsequent influence of the local disease, depresses the vital energies beyond recovery, or the power of reaction, the extension of disorganisation, and the sinking of the manifestations of life throughout the œconomy, are remarkably prominent. Where either the cause or the local disease is less overwhelming, relatively to the state of constitutional power, reaction takes

place, and efforts are thereby made to resist the progress of the local and general mischief. Violent pain, and other severe nervous symptoms, whether occasioned by the nature of the exciting cause, or depending upon the state of the system, may attend any of the varieties of constitutional affection — either that of continued depression, or that of vascular reaction. Where the nervous sufferings are extreme, the vascular system usually evinces some degree of excitement, but it is often slight and without power. In certain cases, the reaction is as excessive as that marking the second variety of constitutional affection (§ 63.); is accompanied with the same symptoms, and runs a similar course; the only difference being in the greater affection of the nervous system than in it. In other cases, vascular excitement is not sensibly raised, unless in so far as the great rapidity of the pulse may indicate it, as in the third variety (§ 65.). In either case, the cerebral disturbance is great, and the disease tends rapidly to an unfavourable issue, if not arrested by active means.

67. If *blood* be taken in any of the varieties of asthenic inflammation, it either does not coagulate, assuming a treacly appearance, or it coagulates imperfectly, the crassamentum being loose; or the imperfect coagulum consists, in its upper half, of a mass resembling jelly in colour and consistence, the lower half containing the colouring matter. The blood, however, may present other appearances, particularly those already noticed, and those described in the article BLOOD (§ 110. *et seq.*). Venæsection, in these states of disease, is generally prejudicial, although, in some of the cases, where the vascular reaction is great, local depletions are often serviceable by unloading the distended capillaries, and diminishing local tension.

68. ii. PROGRESS AND DURATION. — *A*. The *course* of asthenic inflammations is usually acute; and, unless controlled by salutary agents, is generally to an unfavourable termination. Whilst these inflammations most frequently originate in causes which are septic or poisonous, and depressing relatively to the power of the constitution; they also sometimes follow the more sthenic forms of morbid vascular action, in consequence either of the exhaustion following excessive reaction, or of the operation of sedative influences or contaminating agents. Hence, persons affected with sthenic inflammation, especially of a part exposed to the air, will have it changed to the asthenic form, soon after removal to the crowded wards of an hospital, or to any impure or unhealthy situation; and a similar change will also occur in visceral or internal inflammations, from any depressing influence, moral or physical. On the other hand, *asthenic* inflammations are often converted into the *sthenic*, by restorative means acting upon either the respiratory or the digestive functions. Indeed, the principal indication of cure in the former, is to change them to the latter by such means; but, in order that this end should be accomplished, they must be energetically and appropriately employed. Repeated efforts at restoration, in respect both of the local lesion and the constitutional disturbance, are often made during the course of asthenic inflammation, especially when the treatment is only partially calculated to attain its objects; and the disease thus assumes a remittent appearance, and is much prolonged. When a morbid secretion, or fœtid pus, collects in a part which is deep-seated, although a favourable change may seem to have taken place, from the treatment, all the symptoms, local and constitutional, are sometimes speedily and unexpectedly aggravated, and the patient ultimately sinks. Occasionally, efforts at restoration recur oftener than once, before either recovery takes place, or death ensues. This is especially the case when the disease is caused by the inoculation of an animal secretion or poison; the inflammation extending along the cellular tissue, lymphatics, or veins, sometimes with occasional interruptions to its course, and with short ameliorations of the nervous and general disturbance, until the trunk of the body is reached, when all the symptoms become suddenly aggravated: vomiting, delirium, lurid and collapsed countenance, exhaustion of vascular and nervous power, laboured respiration, clammy perspiration, singultus, &c., appear, and the patient sinks.— Upon *dissection*, collections of fœtid pus, disorganisation of the cellular tissue, and lesions of the lymphatic and circulating vessels, are found extending to the central parts of the frame. The neighbouring cavities also contain effused fluid of various appearances, and the parenchymatous viscera purulent collections; the serous membranes being more or less inflamed, or partially adherent.

69. *B*. The *duration* of asthenic inflammations varies from a day or two to several weeks. It may not be longer than the former period in the puerperal state, and it may be prolonged to the latter in the recurring or remitting form of the disease. It is also often of very short duration, when caused by septic or contaminating animal matters. In many cases, however, when the spreading characters of the local disease, and the adynamic type of the symptomatic fever, have been arrested, a suppurative state of action continues for a considerable time, until more or less complete reparation of the affected part is accomplished. Indeed, this is generally the case when much disorganisation has taken place before the disease is arrested.

70. iii. COMPLICATIONS. — Asthenic inflammations frequently occur in the course of other diseases, particularly of exanthematic, continued, and adynamic fevers. It is chiefly when exanthematic fevers assume an adynamic form, that the inflammations which complicate them are truly asthenic. In the inflammatory type of these fevers, the associated local alterations possess more of the sthenic characters. The same applies to continued fevers; the adynamic species being those in which the asthenic states of local action, and of structural change, are chiefly observed. Indeed, asthenic inflammations frequently appear in the course, and even constitute a principal part, of all infectious, malignant, and contagious maladies. In these, they present, generally, modified or aggravated characters; but still they are merely varieties of this state of local morbid action, depending upon the specific nature of the cause, and of the constitutional affection. This is exemplified by scarlatina, small-pox, plague, &c. The course of most of these specific forms of asthenic inflammation is very acute; the complication often accelerating a fatal issue.

71. iv. TERMINATIONS and CONSEQUENCES.—*A*.

Asthenic inflammations *terminate*—1st, in a return to a healthy state of action;—2dly, in sphacelation or disorganisation; — and, 3dly, in dissolution without sphacelation, or without disorganisation so extensive as to be of itself productive of death.—*a. A return of the healthy state* of action is generally brought about by constitutional or local means, — by the former especially, or by both, — which are calculated to restore the vital powers, to impart tone to the relaxed capillaries and tissues, and to enable the part to secrete a more healthy pus, and to form coagulable lymph, by which the extension of the morbid action may be prevented. Thus it is necessary that the asthenic state should be changed into the sthenic before restoration can be accomplished; and this can be affected only by such means as will change the constitutional commotion from the adynamic type, — as will give energy to the organic nervous system, at the same time that they restrain excessive vascular action. As soon as the local disease and accompanying fever assume the sthenic conditions, reparation commences, and recovery takes place, as in these inflammations (§ 39.).

72. *b. Sphacelation* or *disorganisation* of the affected part may take place in very various grades. After the occurrence of either, the inflammation and disorganisation may cease to extend; the local action and febrile commotion may gradually or quickly assume a more sthenic character, particularly under restorative influences; the sphacelated portion may be thrown off, the disorganised part repaired, a suppurative action set up, and coagulable lymph thrown out around the seat of suppuration, whereby the surrounding structures will be protected, and the diseased parts more or less restored. Very frequently, however, when asthenic inflammations terminate in this way, the local mischief increases rapidly, and the general disturbance is aggravated, until life is at last extinguished. In these cases, the destruction of parts, either by sphacelation, or by phagedenic or sloughing ulceration, is generally so extensive, as to be incompatible with the continuance of life; but in those next to be noticed, the destruction of parts is not of itself sufficient to produce death.

73. *c. Dissolution, without sphacelation, or disorganisation,* so extensive as to account for the occurrence, is not an infrequent termination of asthenic inflammations. In such cases, the local affection is either merely the local manifestation of a severe constitutional malady, or is attended by a state of vital depression or exhaustion so extreme, as to terminate life, before it had advanced to the changes constituting actual disorganisation. In some of these cases, the result depends chiefly upon the morbid impression first made upon, and continuing to influence, the organic nervous energy, and in others it is partly owing to the morbid state of the blood, arising either from the same source, or from contingent circumstances or changes. When serous or mucous membranes are the seat of asthenic inflammation, a fatal termination is owing rather to the vital depression consequent upon the extent of surface to which the morbid action has been extended, than to the amount of disorganisation. This is evinced in many cases of general *peritonitis.* When a mucous surface engaged in the performance of vital actions is the seat of the disease, the powers of life often sink rapidly, both from the extent of surface affected, and from the interruption to the functions performed by it. This is shown in general *bronchitis*, and in certain states of *influenza.* Illustrations, moreover, of this termination of asthenic inflammations are often furnished by certain of the forms of disease caused by poisoned wounds, or by local injuries, and by some cases of *puerperal disease*, and even of *erysipelas* *, particularly when occurring in an infectious or epidemic form.

74. *B. Consequences.*—Asthenic inflammations give rise to certain changes which differ in some respects from those attending the sthenic form of the disease. It is necessary in practice to be fully acquainted with the differences between the results of both states of inflammation, especially as they are often so slight as to be overlooked, and as these results are generally essentially the same, but modified in character and in the period of their appearance. — *a. Effusion* of serous fluid is a very early consequence of asthenic inflammations. In parenchymatous or cellular parts it produces the extreme swelling (which is in some cases and situations œdematous or quaggy) attending the disease; and, in serous membranes, it often takes place to a great extent, and is in all respects an *effusion*, rather than an *exudation*. The appearance of the effused fluid varies much with the state of the disease, and with the degree of vital power and vascular reaction. In proportion as power is depressed, is the effused fluid ichorous, foul, abundant, and dark or discoloured; probably from some of the blood-globules, or of the colouring matter, having been effused with the serum. Hence it is, in some instances, almost sanguineous. As vascular reaction is increased, the fluid is turbid, flocculent, sero-albuminous, or sero-puriform; the situation and other circumstances attending upon the effusion modifying its character. The puerperal state, and the persistence or suppression of the discharges and secretions attending this state, modify remarkably the characters of the effused fluid, as in the asthenic peritonitis associated with adynamic puerperal fever. The fluid effused from the mucous surfaces is also much modified from that exuded during sthenic inflammatory action: it is usually less mucous and less albuminous, and more watery, serous, ichorous, or sero-sanguineous, as in cases of adynamic Dysentery (see § 26, 27.). It is sometimes glairy as well as watery; and when vital power is extremely depressed, it is very dark-coloured, offensive, and sanious. When sthenic inflammation passes into the asthenic state, owing to failure of the powers of life, or to morbid states of the blood, the effused fluids also pass from a consistent and coagulable, to a fluid and ichorous, state. The fluid, effused during asthenic inflammation of cellular parts, also partakes more or less of the characters just mentioned. It is deficient in albumen or coagulable lymph, and hence more readily infiltrates the surrounding tissues; and when it is of an ichorous nature, it seems to contaminate the parts to which it extends. Thus asthenic inflammation of cellular tissues is never limited by the effusion of coagulable lymph, unless a change be

---

* In 1836, erysipelas prevailed most generally and fatally in the Orkney Islands. Its infectious nature was fully demonstrated on many occasions. It assumed a low or adynamic form, and the deaths from it were more numerous, for the period of its continuance, than from any other disease that had prevailed within the memory of the oldest practitioner.

produced in the general and local disease by means hereafter to be pointed out; and then lymph is formed around the seat of morbid action, agglutinating the areolæ of the tissue, and becoming a barrier between the morbid matters effused in the central diseased parts, and the healthy structure.

75. *b. Softening* is the next early consequence of asthenic inflammation, and one of the most remarkable. It is evidently owing to the extreme prostration of vital power in the part, causing a loss of the vital cohesion of the tissues, progressive with the disease. I have seen the softening so extreme, that the structures have been torn with the utmost ease after death, although the examination was made whilst the body was still warm. When this state of morbid action affects cellular and mucous parts, the softening and want of cohesion are equal to that of wet bibulous paper. They are often also very remarkable when the serous membranes have been implicated. In some cases of infectious puerperal fevers, complicated with asthenic peritonitis and hysteritis, I have found the peritoneum, and even the substance of the uterus, not only discoloured, but so softened as to be torn with the utmost ease.

76. *c. Suppuration* of a truly restorative nature is met with chiefly when the morbid action verges towards the sthenic type. Purulent matter is frequently found in parts asthenically inflamed, and is often secreted from surfaces thus affected; but it is generally offensive, and otherwise modified from that described above (§ 47.). It is often tinged, particularly in cellular and mucous parts, with the colouring substance of the blood. As the puriform matter, secreted by this state of action, is not confined from the adjoining structures by the effusion of coagulating lymph, and by the cysts thereby formed, it is frequently partially absorbed into the circulation. It thus contaminates the blood, and aggravates both the constitutional and the local disease, — rendering still more morbid the secretions and excretions, as well as the discharge from the seat of inflammation. When the matter passes to a more perfect pus, the change depends upon an improvement in the local and general action, and is an indication of commencing restoration, if unfavourable influences do not come into operation. Mucous and serous membranes often secrete a puriform fluid, presenting characters, varying with the states of vital power and of vascular action, when asthenically inflamed, and generally in a very large quantity. The asthenic bronchitis attending severe cases of *influenza* generally gave rise to a copious secretion of a thin muco-puriform fluid; and the effusions into shut cavities, in some cases of complicated erysipelas, of puerperal fever, &c., consist of a sero-puriform matter, occasionally tinged with blood, or otherwise modified.

77. *d. Ulceration* from asthenic inflammation is characterised by a rapid loss of substance, and its consequent extension. The edges and bottom of the ulcers are softened; sometimes not materially, if at all, elevated; and occasionally not much discoloured, or even inflamed. In other instances they are foul, dark, phagedenic, or sloughing. The discharge from the ulcers is usually ichorous, sanious, sometimes slimy and watery, and always offensive. The loss of substance is in them more owing to deprivation of the vital cohesion of the tissues at the diseased surface, and to the liquefaction or admixture of the dead molecules in the fluid discharge, than to absorption; which, however, takes place to some extent. When the ulceration is sloughy or gangrenous, and the discharge copious and very offensive, it is chiefly owing to the former. In some of these cases, the loss of vital power and cohesion is much more rapid than the solution of the molecules in the discharge, and then large sloughs cover the ulcerated parts. In some instances, the sloughy appearance proceeds from the more consistent or albuminous portion of the discharge having attached itself to the surface, whilst the fluid part either is dissipated by evaporation, or has passed off. This, however, is observed chiefly when a change to a more sthenic action takes place in the inflamed tissues. When absorption proceeds rapidly on the ulcerated surface, the constitutional symptoms are thereby greatly aggravated, and an unfavourable termination accelerated. Asthenic inflammations of the mucous surface, and particularly of that of the bowels, are often followed by ulceration, which occasionally presents a sloughing or phagedenic appearance. (See DYSENTERY, § 54. 56.)

78. III. MODIFICATION OF INFLAMMATION BY STRUCTURE. — Inflammation has been considered above, chiefly with reference to vital power and vascular action, without, however, overlooking the modifications depending upon structure. On this latter part of the subject, a very few general remarks may yet be added. — Dr. C. SMITH first ascribed the differences of inflammation to differences of tissue; and the writings of BICHAT, PINEL, BÉCLARD, GENDRIN, and others, have tended to give very general currency to these views, and to carry them much beyond their legitimate value. Structure certainly modifies, not only the course and terminations, but also the results or products of inflammation. But still the chief sources of difference are, the states of vital power and of vascular action. Besides, inflammation of an organ or part is not limited to a single constituent tissue of that organ, although it may have originated in one tissue only. It usually implicates two or more; although the cellular tissue, being, as it were, the matrix of the rest, is that chiefly affected. When inflammation thus extends to different textures, its characters, terminations, and consequences are modified more by the vital conditions above insisted upon, than by differences of structure; and, even when very differently organised parts are affected, the consequences of the morbid action in all of them are often very nearly the same, and are obviously owing chiefly to the states of vital power and vascular action. Even when mucous or serous surfaces are inflamed, the morbid action is seldom confined to them, the connecting cellular tissue being more or less implicated, and frequently also the adjoining structures; but the results and terminations of this action chiefly depend upon the constitutional affection; or, rather, the local and the general disease are both consequences merely of the morbid states to which they have been just ascribed, and are hence more intimately dependent upon them than upon other circumstances. In the present day, so much has been imputed to structure and to its modifications, natural and morbid; and alterations of function, of

sensibility, and of action, have been so generally connected with lesions of organisation, both by teachers and writers, as to mislead those who are seldom at the trouble of thinking, for themselves, or of attending to the suggestions of common sense in medical observation and reasoning. Organisation, function, and disease are so frequently viewed in connection; and function is so generally considered as resulting from structure, and disease from alterations of structure, that the principle which not only endows, and regulates, and controuls, and ultimately arrests, the functions, but also alters the whole organisation, is left out of the question; and the results of observation in respect of its various conditions and agencies — the circumstances which modify these conditions, and which change its manifestations in the various organs, either from healthy to morbid states, or from the latter to the former — are either insufficiently appreciated, or entirely neglected. Too much is ascribed to the material and gross effects, whilst the conditions out of which they arise are kept out of view, in respect both of their primary operation, and of their continued influence.— It is unnecessary to add any thing to what is advanced on the modifications of inflammation by structure, in the various articles where the pathology of the different tissues and organs is fully discussed.

79. IV. Diagnosis.—*Inflammation may exist in internal parts without being evinced by the usual local and general symptoms*; *and the parts affected by it during life may present very few or even no indications of it after death*; whilst *some affections closely resemble inflammation, and certain appearances very nearly approach those produced by it in the tissues.* To each of these points the *diagnosis of inflammations in general* has especial reference.

80. *A.* Inflammation may be so *latent*, or so *obscure*, owing to the absence of the most important symptoms, and to its seat, as to be recognised with great difficulty. The more slight and chronic forms of inflammation are those most frequently latent or concealed; yet, the most acute states, especially of an asthenic form, and occurring in states of the system characterised by impaired sensibility, or in viscera whose organic sensibility is naturally low, are often latent or obscure. These *concealed inflammations* have been noticed by Hoffmann, Baglivi, Stoll, Weinholt, Mayer, Meckel, Reyland, and Hartmann, and been frequently observed in certain epidemics. They are more common in some organs than in others, especially in the course of adynamic and typhoid fevers, and in other complications. Although they may be expected to exist chiefly, if not altogether, in parenchymatous structures, where the organic sensibility is the most obscure, yet they are not infrequent in serous and sero-fibrous tissues, which are usually acutely sensible in the inflamed state. A morbid condition of the blood, as well as a generally impaired state of sensibility, seems to diminish sensibility in inflamed organs; for the *consecutive* or *secondary inflammations*, which proceed from pre-existing inflammation or disease, are commonly latent or concealed. — *a.* Epidemic fevers are very frequently complicated with acute asthenic inflammations, which seldom betray themselves during life, owing both to the depressed state of organic sensibility, and to the condition of the blood. The brain, the lungs, the liver, the kidneys, the digestive and the respiratory mucous surfaces, are the most liable to be thus affected, without indicating, upon the strictest examination, the extent of mischief; even auscultation, percussion, and pressure, often failing in furnishing the usual evidence of it. Inflammations, however, of the respiratory organs would much more frequently be concealed, if these means of investigation were not resorted to. Indeed, in fever, in influenza, and in various epidemics, pneumonia would almost always be concealed without these aids. Inflammation of the abdominal viscera, during these and other maladies, often, also, does not become manifest, unless upon the strictest examination of the stools, the urine, and the patient's position in bed; and upon the closest observation of the effects of pressure, &c.

81. *b.* Inflammations of serous and sero-fibrous structures are not infrequently latent, especially when they commence gradually and proceed slowly, or when they appear under the same circumstances as have just been mentioned. Pleuritis and pericarditis, in chronic forms, and as complications of febrile or epidemic maladies, are often concealed; and, although less frequently so when auscultation and percussion are employed, yet they often escape detection, especially when they give rise to little effusion, until disclosed by examination after death. The same is observed, although much less frequently, with respect to peritonitis, which, however, often supervenes in more or less obscured states in the course of adynamic fevers. — *c.* Concealed or obscure inflammation of mucous surfaces, especially of the digestive, is remarkably common. Many of the disorders attributed to disturbed function merely, are actually slighter states of inflammation. But much more severe and even acute forms of the disease may exist in this tissue, without the usual evidence of them having been furnished; and may run on to disorganisation and even to death. This, however, chiefly occurs in the course of continued fevers, and in the other circumstances just mentioned.

82. *B.* Various *febrile diseases*, and *painful* and *spasmodic affections*, so closely resemble inflammations as to be distinguished from them with difficulty. — *a.* Several internal inflammations are liable to be mistaken for the more *sthenic forms of continued fever*; and that is the more likely to occur when the latter become complicated, particularly at an early period of their course. But internal inflammations, especially those of a sthenic character, present, amongst the earliest phenomena, some, at least, of the principal symptoms of inflammation, even before the chills or rigors take place, which usually attend their development. The disease is strictly local from the commencement, and is not attended by the vital depression, and loss of muscular power, which not only accompany, but also precede, idiopathic fever. In the former, the fever is sympathetic of, and contingent upon, the local affection; in the latter, the inflammatory complication is a contingency or accident, arising either soon after the commencement, or in the course of the constitutional malady.

83. *b. Painful affections* of internal or concealed parts are liable to be mistaken for in-

flammation. But violent pain is not always an attendant upon inflammatory action, and unless in very acute cases of pleuritis and peritonitis, the pain of inflammation is seldom so severe as that which is dependant solely upon nervous disorder. It is only when the pain is attended by increased vascular action and heat of skin — by symptomatic fever, or, at least, by some degree of vascular excitement; by heat or tension in the vicinity of the pained part; and by a white, loaded, furred, or excited state of the tongue, and high-coloured urine; and when it is increased by pressure; that it becomes an indication of inflammation. The pain of nervous disorder is intermittent or remittent; it often suddenly ceases for an indefinite time, and as suddenly re-appears. It is not attended by a sense of burning, or of heat or of throbbing, and it is generally eased by firm pressure; whereas the pain of inflammation, when severe, becomes gradually so, is continued, although often exacerbated at times — is frequently throbbing, and is always associated with very marked disturbance of the functions of the pained part.

84. *c. Spasmodic disorders* are often referred to inflammatory action; and about twenty-five years ago, when blood-letting was the alleged cure for every thing, and for these disorders especially, they were firmly believed to proceed from this source. However, like painful affections, they are more frequently purely nervous, or independent of inflammation. It is true that they may be complicated with one or other of its forms, and that either painful or spasmodic affections may proceed from congestion, or active determination of blood to the organs thus affected, or to parts in their vicinity; but still these are not inflammation. Both classes of disorder most frequently proceed from some unnatural excitement or irritation at the origin, or in the course either of the nerves supplying the painful or convulsed part, or of those connected with them. Thus irritation of the intestinal or uterine nerves will produce pain or spasm, or both, in remote parts, by their *direct* and *reflex sympathy:* and the irritation of calculi in the kidneys will occasion colic by the *direct sympathy* of the ganglial nerves, and pain or spasm of distant voluntary parts, by the *reflex sympathy* of the cerebro-spinal nerves. (See *Direct and Reflex Sympathy*, in my Edition of RICHERAND's *Elements of Physiology*, edit. 1824, and 1829, p. 546.)

85. *d. Determination of blood* to particular organs may also be confounded with inflammation; and it may run on to the more sthenic forms of the disease, either in acute or in chronic states. But care should be taken to distinguish between them. I have, in the article BLOOD (§ 25.), entered fully upon the consideration of *local determination of blood*, and upon the differences between this affection and *inflammation;* and have shown, that whilst the *first* of these consists only of augmented circulation and functions of a part, and is unattended by symptomatic fever, or any other alteration, the *second* is an actively morbid state of the organic nervous influence, and of the vessels of a part, accompanied by symptomatic fever, and tending generally to change of structure, and often to disorganisation. In the *former* the functions are usually increased, or inordinately excited, the organic sensibility being either unaffected or not sensibly excited; in the *latter* the functions are rarely increased, but always much deranged, or entirely suppressed — organic sensibility being early excited or disordered, and generally sensibly disturbed. (See art. BLOOD, § 25—33.)

86. *e. Congestion of blood* in one or more organs has also been mistaken for inflammation, both during the life of the patient, and in examinations after death. In the article CONGESTION, I have defined it to be deficient vital tone or power, chiefly of the veins of an organ or part, occasioning accumulation of blood in them, and a languid or retarded circulation, the functions of the organ being thereby proportionately disordered. The pathological relations, terminations, appearances, and symptoms of this form of disorder, are there so fully described, that it is unnecessary to notice, at this place, the distinctions between it and inflammation, farther than that, in the *former*, the functions of a part are generally more or less impaired, without the organic sensibility being morbidly excited, and without symptomatic fever being present; in the *latter*, there is not only disturbance of functions, but also exalted or disordered sensibility and vascular action, and more or less febrile commotion. The one is a morbid state of the capillaries and arteries, originating in the organic nervous influence of a part, with which state the system generally sympathises; the other is an engorgement of the veins, sometimes extending to the capillaries, owing either to a mechanical obstruction to the return of blood through the former, or to deficient vital energy of the affected organ. — The blood in congested capillaries and veins is of a purple or black hue; whilst that in the capillaries of inflamed parts is much more red or florid. (See art. CONGESTION OF BLOOD.)

87. C. There are *certain appearances observed after death*, which are often difficult to be distinguished from those consequent upon inflammation. — *a.* The *congestion of blood* from mechanical obstacles to the circulation in the veins will not be mistaken for inflammation, if the exact state of the congested tissues, and if the course of the venous trunks, be carefully observed. It is in mucous membranes especially that the diagnosis is at all difficult, and in them only when the redness presents a ramiform appearance. In congestion from this cause the veins are full, often tortuous, and rarely varicose, — states not existing in inflammation; and the obstruction is commonly organic disease of the liver, or of the heart, or of the lungs, or the pressure of some tumour on large veins. Mechanical congestion sometimes, however, gives rise to inflammation, or is associated with it, and then the difficulty of diagnosis is much increased; but the state of the tissues, the capillaries of which are thus congested, and the presence of one or other of the usual consequences of inflammation, will generally lead to a correct conclusion. Dr. MACARTNEY mentions, in his work on *Inflammation*, which appeared as this article was passing through the press, that the arteries of a congested part are smaller than natural, and that he verified the fact by experiments; the corresponding arteries to the veins, which were congested by tying them, being very much reduced in size.

88. *b. Congestion from position or gravitation* is much more likely to be confounded with inflam-

mation, than that produced by mechanical obstacles; but attention to the relative situation of the congested part, especially with reference to a depending position and gravitation of the fluids, will generally aid the observer. When congestion of the capillaries is present, where gravitation could not aid in causing it, and when there is no manifest mechanical obstruction of the veins, it must be ascribed to inflammatory action, although the usual consequences of such action are absent, for the inflammation may have been too recent to have given rise to them.

89. *c. Redness from inbibition*, or from the dyeing of the internal coats of vessels by the colouring matter of the blood is sufficiently discussed in the article on *Diseases of* ARTERIES (§ 38.). It is of a scarlet red; is limited to the lining membrane of the vessels; and is unconnected with any change in them, or with any capillary injection, or congestion of the vasa vasorum: whereas inflammatory redness in the internal surface of vessels is less uniform than it; is more dull or pink coloured; extends to all the coats, although in different degrees; and is accompanied with capillary injection, with softening and opacity of the inner membrane, with thickening, serous infiltration, &c. of all the tunics.

90. *d. Inflammation sometimes leaves no marks of its existence after death.*— This occurs chiefly in the inflammatory affections of the skin, and in slight or incipient inflammation of serous membranes. But the redness attendant upon the disease is more frequently diminished after death, than altogether banished. The inflammatory redness of the skin, and mucous and serous membranes, attending the exanthemata, and continued fevers, often partially or wholly disappear after death: yet these structures present appearances which may be inferred to have resulted from inflammation, and to have been associated with redness and vascular injection during life, even although the fact had not been demonstrated to the senses. When the skin has been affected, it usually assumes a purplish hue in the seat of affection, and the cohesion of the cuticle to the subsequent tissue is early diminished, so that it soon may be detached with ease. The vital cohesion also of mucous and serous membranes is impaired more than is usually observed, although all redness has disappeared, and, in these parts, as well as in the skin, and cellular tissue, decomposition makes a more rapid progress than in the healthy structures. Vascular injection and redness may have vanished more or less, even in situations, and in forms of inflammation, where some one of the usual consequences of the disease is present. In this case, however, there can be no doubt of its nature.

91. V. CAUSES OF INFLAMMATIONS.—i. CONSTITUTIONAL AND PREDISPOSING CAUSES.—*a. Age* has considerable influence upon the production and progress of inflammation. The disposition, particularly to the more sthenic and acute forms of the disease, is greatest in childhood and youth. It may be said to diminish gradually from infancy to old age, whilst the more chronic and asthenic states become more frequent as age advances. The brain and membranes, the lungs and mucous surfaces, the skin, the serous surfaces within the thorax, and the glands, are the most frequently affected in children and young persons; and the digestive, respiratory, urinary, and generative organs, at more advanced epochs of existence, and generally in the order in which they are here enumerated.

92. *b. Sex* has but little influence in predisposing to inflammation. Males are more frequently affected, chiefly because they are exposed more than females to other predisposing, and to many of the exciting, causes. Females are most predisposed to inflammation at the commencement, during the continuance, and for some time after, the disappearance of the catamenia, and during the puerperal states, especially after parturition.

93. *c.* Of *temperaments* and *diathesis*, the most influential are the sanguineo-melancholic and irritable; the scrofulous, gouty, and rheumatic. It is chiefly owing to the descent of temperament and diathesis to the offspring, that inflammations sometimes present an *hereditary* tendency.

94. *d. Habits* and *modes of life* dispose to inflammations of various organs. Persons who are exposed to the open air, and to atmospheric vicissitudes, or who take active exercise in the air, are liable to inflammation of the respiratory organs; and inflammatory diseases generally assume a sthenic or acute character in them. Those who are indolent, sedentary, or confined to warm or close apartments, and unhealthy localities, are most subject to inflammations of the digestive, parenchymatous, and excreting viscera, particularly the excreting organs in the abdomen; the morbid action very frequently assuming either asthenic or chronic forms. — The influence of *modes of life* in predisposing to, and exciting, inflammatory maladies, is fully shown in the article on ARTS AND EMPLOYMENTS.

95. *e. Food and drink.* —The liberal use of animal food favours the occurrence of every form of inflammatory action, or generates an inflammatory diathesis. It is even very probable that certain kinds of animal food predispose to morbid vascular action in some structures in preference to others. The frequent or habitual use of pork seems to dispose chiefly to inflammations of the glands, joints, and bowels; and aids in generating a scrofulous diathesis. The laws of MOSES, with reference to animal food, have evidently had a salutary influence in rendering scrofulous, gouty, and inflammatory diseases less frequent among the Jews than in any other class of the community. In warm climates especially, the use of pork, and of the viscera and blood of animals, cannot fail of being prejudicial; and there cannot be a doubt that the proneness to inflammations among Europeans, in hot climates, arises chiefly from the quantity of animal food and exciting liquors consumed by them. Persons who live much upon fish are liable to inflammatory affections of the skin and digestive mucous surface; and, whilst flesh meats favour, in temperate climates, a sthenic form of inflammatory action, living much on fish disposes chiefly to the more asthenic and chronic states.

96. Exciting or *intoxicating beverages* predispose to, and often directly excite, inflammation, particularly of the digestive and urinary organs. The habitual use of these liquors frequently induces and keeps up morbid vascular action, chiefly of these parts, of a sub-acute or chronic kind, generally passing into confirmed structural change. These effects most commonly follow the use of spirituous liquors; and, next to these, new wines

and malt liquors are most prejudicial. Persons who use much of the former soon become subject to enlargements and obstructions of the abdominal viscera, consequent upon repeated or protracted inflammatory action; and those who drink the latter in large quantities, and who, at the same time, are very actively employed in the open air, as coal-heavers, draymen, &c., are liable to the most acute attacks, often attended by the most violent constitutional commotion, and terminating rapidly in disorganisation of the inflamed part.

97. *f. A plethoric habit of body,*— the more immediate consequence of diet and regimen,— remarkably favours the occurrence of inflammations. Persons who live fully, and take insufficient exercise, are extremely prone to these diseases, when exposed to atmospheric vicissitudes, and to cold, particularly if the body is quiescent, as when a person is carried rapidly through the air in an open carriage. Persons in large towns or cities, accustomed to warm close rooms, or engaged in sedentary occupations, and living fully, when called to a distance, often travel on the outside of coaches, or in open carriages, and are surprised when they are attacked by inflammations, the slighter forms and earlier stages of which they usually neglect. The surprise would have been, if they had escaped. In the article BLOOD, where the subject of vascular plethora and determinations of blood are discussed (§ 13. *et seq.*), I have shown how much fulness of the vascular system disposes to inflammatory action, and how frequently the latter follows as a consequence, or as a higher grade, of the former. When this system is overloaded, some part is liable to experience over-distention and augmented flux, which often soon passes into morbid action, the balance of circulation being readily disturbed by external and internal — by physical and mental, causes. In the article referred to, I have stated the connection often existing between congestions, general and local plethora, local determinations, and inflammations. Congestions and local plethora are frequently dependent upon the state of the venous circulation; and this upon obstructions in the liver, lungs, or heart; the efforts made to propel the blood in the capillaries, particularly under the influence of stimuli, readily inducing inflammation, especially of an asthenic kind. These states of vascular fulness, thus originating and predominating in the veins, are most common in persons advanced in life. On the other hand, local determinations of blood proceed chiefly from capillary expansion and arterial action, without venous obstruction; are most commonly observed in the young and those in the prime of life; and most frequently pass into the sthenic forms of inflammation.

98. But there are other states of the vascular system, upon which as much, probably, depends, not only in disposing to, but also in exciting, morbid vascular action, as upon vascular fulness; and to which very inadequate attention has been paid. These are the accumulation of effete and hurtful materials or elements in the blood, owing to imperfect depurating function. When the excreting functions of the kidneys, of the skin, of the liver, and even of the large bowels, are inadequately performed, the excess of hurtful, highly animalised, and irritating substances in the blood, as urea, &c., both predisposes to, and excites, inflammation in parts most susceptible of this cause of irritation, from previous disorder, or peculiarity of structure, or function. Irritating matters also may be carried from the digestive organs, or other parts, into the blood, where they may act in a way similar to those just mentioned. Thus inordinately exciting articles of food or drink, accumulated excrementitious matters in the biliary organs and intestinal canal, and morbid secretions pent up in any part of the body, are often absorbed into the circulation, and produce inflammations, varying in character with the kind of morbid matter producing it. (See art. ABSORPTION.)

99. *g.* The *influence of the digestive organs* in the production of inflammations has been acknowledged, since it was insisted upon by JOHN HUNTER. But it is very probable, that the disorder of these organs, thus predisposing to inflammations, and the predisposition itself, are associated effects of deranged organic nervous influence. There can be no doubt, however, that when the functions of the stomach and bowels are disordered or impaired, and when the liver is torpid, and accumulations of bile are formed in the biliary ducts or gall-bladder, a predisposition to inflammations is not only thus induced, but also a greater tendency to asthenic action is thereby generated. The state of the digestive organs often indicates the degree of organic nervous power attending upon the disease; whatever deranges their functions, or aggravates existing disorder in them, increasing the general and local affection, and changing sthenic to asthenic action. The disorder induced in the organs of digestion generally extends to the organs of excretion, not only by the direct sympathy arising from nervous endowment, and from the dependence of both classes of organs upon the same nervous influence, but also by the changes produced by the former in the circulating fluids,— the predisposition to morbid vascular action being accordingly heightened.

100. *h. Mental emotions* also favour the occurrence of inflammation, when excessive. Violent fits of passion may even excite the disease, particularly in the brain, liver, or heart. The depressing passions, when extreme or of long continuance, induce the more chronic or asthenic states of morbid action, or cause the sthenic disease to assume either of these forms. The exhaustion consequent upon protracted or excessive nervous sensibility, and upon pain, has a similar effect. When pain is very violent, it seems to act like to concussion of the nervous masses or of the body, and to severe crushing injuries or wounds: — they all depress organic nervous power, and, when inflammation takes place, give rise to an asthenic or spreading form of the disease.

101. *i.* A predisposition to inflammations is often inherent in the frame from *hereditary conformation* or temperament (§ 93.), and from *previously disordered states* of certain organs or tissues. Parts which have been formerly inflamed are most prone to experience a recurrence of the disease. Organs which are liable to simple excitation, or to actively increased function, are generally much disposed to the different grades of sthenic inflammatory action; whilst those which are torpid, debilitated, or exhausted, are most prone to the asthenic states. Persons whose mental faculties have been inordinately exercised, are most disposed to inflammations of the brain and their consequences; and

those who have over-excited or exhausted the digestive organs, by too much or too rich food, and by intoxicating liquors, are most liable to inflammatory affections of the stomach, liver, and bowels.

102. *k.* The influence of *temperature, season, and climate* is shown, not only by their favouring the appearance, but also by their modifying the characters and forms, of inflammations. High ranges of atmospheric heat produce inflammations of the liver, stomach, and brain; and, if heat be conjoined with humidity, these diseases assume a low or asthenic form, the bowels being frequently also affected. Prolonged high temperature, especially when aided by humidity, changes the state of blood, affects the biliary functions, and imparts a peculiar character to inflammatory diseases. Thus in autumn, after hot summers, these maladies are frequently associated with marked gastric or bilious disorder; and in winter and spring, when the air is cold and humid, they often present an erysipelatous or catarrhal form. A cold and dry state of the air is generally wholesome, if due exercise be taken; and, without favouring the occurrence of inflammations, imparts to them an acute and sthenic character, the respiratory organs being the most liable to be affected. But there are other conditions of the air, or prevailing atmospheric constitutions, which dispose to inflammations, and bestow upon them, for a certain period, peculiar forms or features. The sources of these have not been ascertained, although they may probably be referred to electrical states and terrestrial emanations. However these prevailing constitutions may arise, there can be no doubt of their influence on inflammations, and of the necessity of ascertaining their nature and effects, as being requisite to an appropriate and successful method of cure.

103. From what has just been advanced, the influence of *climate* on inflammatory diseases may be partly inferred; for as the climate partakes the most of either of the foregoing characters, so will these diseases be prevalent or be modified. In cold, variable, and humid climates, inflammations of the respiratory organs, and the rheumatic and scrofulous diathesis, are most common. In warm humid countries, inflammatory action appears chiefly in the liver, digestive canal, and spleen; and especially when exhalations from the soil also come into operation, it either assumes, or rapidly passes into, asthenic forms.

104. It should be kept in recollection that several of these *causes of predisposition* sometimes act conjointly; that they may be sufficient of themselves to occasion inflammation, although they generally require the more efficient or determining action of the *exciting causes* next to be considered; and that as most of them either continue in operation during the disease, or are inherent in the constitution, *they exert a very marked effect upon the form, progress, and consequences of the disease.* Hence the necessity of ascertaining them fully, and of appreciating them correctly, in order to treat with success the disease they are concerned in causing.

105. ii. The EXCITING CAUSES are very numerous and diversified, but uncertain in their operation, or ascertained with great difficulty. — Many of the predisposing causes, owing to their more intense or combined action, sometimes of themselves produce inflammation; and in such cases, the effect does not always appear in very obvious connection with its real cause. In many instances of visceral inflammation, the exciting cause is very obscure, the disease proceeding rather from a combination of circumstances, — some of them of fortuitous occurrence, — than from any one very obvious agency. The more direct causes may be considered with reference to their *mode of action* in producing the morbid effect: — 1st, Certain of them act by injuring the organisation; — 2dly, Some excite the organic nervous sensibility of the part, and, consecutively, vascular action in it; — 3dly, Others operate by affecting the function and circulation of the organ; inflammation resulting from those alterations in connection with predisposition; — 4thly, Many produce a specific or truly morbid action in the part, changing the organic nervous sensibility, the vascular action, and all the vital conditions, both locally and generally; — 5thly, Morbid matters secreted by an organ, or carried into the blood from a diseased part, may occasion inflammation by their direct effect upon the capillary vessels, as well as in one or other of the above modes; inflammation of one part thus giving rise, by means of some one of its consequences, to inflammation of another; and the morbid secretions from one organ inflaming others, with which they come in contact.

106. *A. The causes which act by injuring the organisation* are chiefly all external injuries, which divide, lacerate, or bruise a part. — Structures cleanly divided by a very sharp instrument are much less disposed to inflame, than those which are lacerated, bruised, or punctured. — *Lacerated parts* undergo much greater injury of organisation than simple division; their nervous fibriles and vessels are torn, and both these constituents of structure are thereby severely affected, the vitality of the part being often either directly or consecutively destroyed, and sloughing frequently taking place. — Violent *contusions* sometimes so disorganise a part as to prevent it from recovering any share of vital action. It then soon dies, and is cast off, or the system sinks under the shock primarily experienced, and the depression consecutively caused by the extent of local mischief, without inflammation having been fully developed. When contusions are slight, they recover without inflammation taking place; but when the capillaries are injured, or when their contents have partially escaped into the tissues of the part, or even when their tone is so much exhausted as to admit of much effusion, and especially when the cohesion of the textures has been more or less altered or overcome, inflammatory action is very liable to occur, although it does not necessarily take place. — *Punctured wounds* readily induce inflammation, and generally in proportion to the bluntness of the instrument. A triangular or round instrument also produces it more readily than a flat and sharp one. The disposition to inflammation from punctured wounds chiefly depends upon their extent, upon the nature of the structures which are implicated by them, upon the quantity of blood effused in the parts which they have penetrated, and upon the state of the constitution. Punctures of tendons, nerves, capsules, and aponeuroses, are much more injurious than of other parts; and the constitutional affection, in relation to the local injury and resulting inflammation, is very much greater. When much

blood is effused without a sufficient outlet, the punctured part being distended by it, and when blood is effused at the bottom of the wound, or in surrounding tissues, inflammation readily takes place, this fluid usually exciting inflammation in parts to which it is naturally foreign. The effects frequently also depend upon the nature of the body by which the puncture has been made. The teeth, claws, spurs, and spines of animals and fishes, generally produce very severe and even dangerous injuries, the punctures inflaming readily and rapidly, although no poisonous fluid has been inserted in them.

107. *Concussions* or severe shocks are often followed by inflammation. The parts which suffer from this cause are chiefly the brain, the spinal chord, the liver, and spleen. It is not only organic nervous power that is dissipated or exhausted in such cases, but the organisation is often more or less changed — minute lacerations of structure, or of capillary vessels, and consequent effusions or ecchymoses, being often found. The suspension of the functions caused by concussion is remarkably prone to pass into inflammatory reaction, when this species of injury does not altogether extinguish them. — Severe or prolonged *pressure* of parts often causes an asthenic inflammation of them, quickly passing into ulceration or gangrene. The *removal* of a gradually increased or continued pressure is often followed by a local and general inflammatory reaction, which in some cases, and as respects certain structures, becomes very acute, as in the peritonitis consequent upon parturition, and upon tapping dropsies of the abdomen. — *Ligatures*, or other causes of constriction, act by impeding the venous circulation; and various *positions* have a similar effect. They also aggravate inflammation when otherwise produced.

108. Various substances affect the organisation of a part, so as to induce inflammation, especially *mineral substances*. When these are applied in concentrated states, they destroy the organisation, inflammation appearing around the injured part. The pure alkalies, the strong acids, and certain of their salts, have this effect. But in weaker states, they inflame the tissues in the mode next to be considered (§ 109.). The bichloride of mercury, arsenious acid, &c., in an undiluted state, decompose or destroy the vital cohesion of the part; but in a weaker state they affect the organic sensibility and vascular action, thereby causing inflammation, and certain of its consequences. — *Extremes of temperature* affect the organisation almost directly, although in less grades; they act chiefly in the manner just mentioned.

109. *B. The causes which excite the organic nervous sensibility and the vascular action of the part*, are all those substances which are classed as stimulants or irritants. They act directly, and chiefly, on the parts to which they are applied. Inflammations of the skin, intestinal canal, urinary organs, and even of the respiratory passages, generally proceed from these sources. Prolonged friction, flagellation, the application of any of the above substances to the skin, or the ingestion of them into the stomach, and high ranges of temperature, produce inflammation in this way. Volatile or diffusible stimulants, irritating gases, and fine particles of mineral or vegetable substances, floating in the air, often inflame the respiratory passages. The atmospheric air, especially the oxygen of it, frequently inflames parts whose organisation is not suited to exposure to it. When the serous membranes of shut cavities are exposed to the *air*, they first become dry; afterwards more vascular than natural; and ultimately covered with a thin exudation of lymph, varying in thickness, and in the proportions of serum and coagulable albumen, with the intensity of vascular action, the constitution of the patient, and the powers of life. Mucous surfaces deprived of their epithelium, the skin without its cuticle, and other exposed or divided textures, are similarly affected; inflammation frequently supervening, unless when the lymph thrown out coagulates over them, and completely protects them from the air; and then the process of restoration usually takes place underneath the protection thus formed. Stimulating substances may be taken into the stomach, and pass from it into the circulation, without materially affecting the digestive organs, and yet they may inflame the organs by which they are excreted. Thus, cantharides and turpentine cause acute nephritis; and spirituous liquors, and the prolonged exhibition of iodine, excite chronic inflammation and organic lesion of the kidneys, giving rise to dropsy. Low ranges of temperature also sometimes occasion inflammation — not, however, by directly exciting the nervous influence and vascular action, but by remarkably depressing both, in the first instance; the consequent reaction proceeding to an excessive, severe, or prolonged state of inflammation. (See arts. Cold, and Gangrene.)

110. *C. The causes which affect the functions and circulation of an organ, aided by predisposition*, are numerous, and, like the preceding class, hardly admit of enumeration. Whatever inordinately excites the natural actions, and thereby the circulation of an organ, or whatever primarily stimulates the vascular action of a part, will frequently occasion inflammation of it; for the increased function or circulation will run on to inflammatory action, whenever a strong predisposition is present in the organ or constitution. The energetic actions of the brain are attended by augmented circulation, which may pass into inflammation. Increased function of the liver is often followed by inflammation of it. Excessive indulgence of the appetite and excitement of the stomach often precede some of the forms of gastritis or enteritis. In these cases, the natural actions are first inordinately excited, and morbid vascular action is thereby induced. But, in other instances, the order of morbid procession is reversed: the causes increase the circulation in the organ before the function is materially deranged. Thus *cold*, instead of benumbing sensibility, and of giving rise to a morbid vascular reaction upon its removal, in external or other parts on which it acts, often determines the momentum of the circulation upon internal viscera and surfaces; and if these be not partially relieved from the load or congestion thereby occasioned, by a free exercise of their functions, inflammation is a frequent consequence. Interruption of the exhalation from the skin, constriction of the surface, and diminished circulation both there and in the extremities, combine to drive the blood upon the mucous surfaces, and parenchymatous viscera; increased function, augmented secretion, or morbid vascular action resulting therefrom, according to the states of constitutional power or of predis-

position, and to the continuance or intensity of the cause. When cold is not protracted or intense, relatively to the constitutional energy and predisposition of the individual, the internal functions, especially those of digestion, and of excretion, the urinary particularly, are increased, and inflammatory action does not take place; but when the internal determination is not relieved by augmented secretion, nor removed by a restoration of the circulation to the surface and extremities, inflammation of the predisposed organ is often the consequence. Sudden, continued, or frequent exposures to cold, vicissitudes of temperature, and partial exposure to currents of cold air, to humidity, &c., are the most common causes of internal inflammation, and especially of the respiratory organs. As respects these organs particularly, it is not the sedative influence of cold, acting upon exhaling surfaces, the seat of active organic functions, but the reaction consequent upon the removal of this influence, that occasions the inflammation; the primary influence of cold only disposing the part to inflame, when reaction takes place, or modifying the reaction, so as to cause it to run on to inflammation. Hence it is that persons, after going into a cold air from a warm apartment, generally escape inflammation of the air-passages, unless they be perspiring, or the predisposition to inflammation be strong, when they avoid a sudden return to a high temperature, by which reaction is liable to be morbidly increased; and hence the greater danger from exposure to much warmth after the prolonged or intense influence of cold, than from the cold without the subsequent injurious action of heat.

111. *D. The specific causes of inflammation*, whereby the organic nervous sensibility, the vascular action, and all the vital conditions are truly morbidly altered, both locally and generally, comprise all infectious, contagious, and contaminating matters, particularly when applied to an abraded surface or wound. Most of the substances forming the second and third classes of *infectious agents* (see art. INFECTION, § 4.), and arranged also under the head of ANIMAL POISONS (see that article), produce inflammation, presenting one or other of the local and general forms described under the asthenic species (§ 54. *et seq.*). The secretions and fluids of one person may excite inflammation when applied, as just stated, to another; but the effect is more certainly produced when these matters are taken from the dead body, and especially when they are the product of inflammatory or other disease. The serous, puriform, sanious, or sero-puriform fluids generated by specific or constitutional maladies, and by diffused inflammations of the peritoneum, or even of other serous surfaces, possess the property of exciting the asthenic or diffusive forms of inflammatory action in a very remarkable manner. The most dangerous effects generally follow the inoculation of these fluids from the recently dead, or from the still warm body, or even the application of them to the skin. The next most noxious effects result from the introduction of animal matter in a very far advanced stage of putrefaction. In both cases, but in the former especially, the constitutional affection is most severe (§ 59.). Even when the local injury is hardly to be perceived, as well as when it is more manifest—vesicles or pustules arising in its vicinity—inflammation extends through the cellular tissue in the course chiefly of the lymphatics or veins, sometimes implicating these vessels, and abcesses form under the muscles, particularly under the pectoral and other muscles of the chest; a great part of the cellular tissue on the trunk, and even the serous surfaces underneath, becoming implicated in the disease. Occasionally the inflammation presents the characters of some one of the varieties of *erysipelas*; the particular form of the local, as well as of the general affection, depending upon the constitution and previous health of the patient, and upon the nature or properties of the animal poison. The most virulent of the morbid poisons seems to be the fluid effused in the large cavities, and particularly that found after puerperal peritonitis, in recently dead bodies. The recent brain, the substance of fungoid, carcinomatous, and medullary tumours, and the sanious fluids proceeding from diffusive, erysipelatous, and gangrenous inflammations, are also frequently productive of most noxious effects.

95. Although the most dangerous form of inflammation is caused by the fluids of the recent human subject, yet those of recently killed *animals* produce no such effect. This probably arises from death being caused in the former by disease, in the latter by bleeding, during a state of health. When, however, the fluids of animals which are either diseased or under the influence of inordinate excitement, or of its more immediate effects, are applied to a wound or denuded surface, the effects are often severe, although not so dangerous as in the former cases. (See arts. INFECTION, and POISONS — *Animal*.)

112. iii. CONSECUTIVE INFLAMMATIONS.—*Morbid matters secreted by an organ, or circulating in the blood, frequently produce inflammation of either neighbouring or distant organs.* — This is an important class of causes, and, like that immediately preceding, generally occasions the asthenic or diffusive forms of inflammation. When the natural secretions of an organ are rendered unusually morbid or irritating, either from perverted action, or from the accumulation of noxious elements in the blood, the canals through which they pass are often irritated and inflamed by them. The morbid bile formed during affections of the liver, or in the course of gastric, bilious, remittent, and continued fevers, often occasion the enteric or dysenteric complications occurring in these diseases. Inflammations of the colon and rectum also often arise from this cause, as well as those of the gall-bladder and bile-ducts. The secretions on the surface of the skin, especially when allowed to accumulate and remain on it, are the most frequent causes of cutaneous inflammation; and alterations of the urine often occasion inflammation of the urinary bladder. Indeed, most of the complications appearing in the course of febrile diseases, arise either from the morbid state of the secreted fluids, or from that of the blood itself; the organic influence being remarkably susceptible of their impressions, and the vascular system being readily excited by them to an increased action, devoid of power or healthy tone. When vital power or organic nervous influence is extremely depressed, as in adynamic, typhoid or exanthematous fevers, the parts with which diseased secretions come in contact are unable to resist the impression made by them, or to throw them off by means of a healthy secretion from their own surfaces, and by sthenic muscular action. Hence, this impression is soon followed by asthenic inflammation.

113. Morbid matters may also be *absorbed* from mucous surfaces, from hollow organs, or from the more solid structures in which they have been formed, and be carried by the lymphatics to glands, and even into the veins and general current of the circulation; and they may, moreover, be formed on the internal surfaces of the vessels themselves, contaminating the blood in either case, or altering it in such a manner as to excite inflammation in various different and distant organs. Sanious or morbid fluids may be taken up from the cavity of the uterus; and, passing into the veins and blood, occasion phlebitis or other forms of malignant puerperal disease. Morbid secretions in the intestinal canal may be absorbed and carried into the blood of the vena porta, and excite diffused or other forms of hepatitis; these results taking place the more readily, the more unhealthy the secretions are that are accumulated in these situations, and the more depressed the vital powers.

114. iv. SECONDARY INFLAMMATIONS.—Morbid matters, also, from *primary* inflammations, may excite *secondary* inflammations, — 1st, In the course of connecting cellular tissues or membranous surfaces; — 2dly, In lymphatics and absorbent glands; — 3dly, In veins; — 4thly, In parenchymatous viscera; — 5thly, In synovial capsules, &c.; — and, 6thly, In serous or mucous surfaces. The secondary disease, in either of these situations, is most frequent when the morbid matters from the primary inflammation are effused in the substance of a part without being confined or limited by a barrier or cyst formed by coagulable lymph, and when organic or nervous power is much depressed. — *a*. The *mode* in which the consecutive or secondary disease is developed, is different in most of these situations, and is perhaps doubtful as respects some of them. When the primary inflammation of *membranous surfaces* or of *cellular or adipose tissues* is asthenic, it is not only disposed to extend in every direction without any break or interval, but it often advances to distant or even remote parts, without the intervals presenting any manifest change, and after various intervals of time. Several states of erysipelas and diffused inflammation of the cellular tissue, and of mucous and of serous membranes, illustrate this. When the extension of the disease is continuous, the nature of the tissue, and the infiltration of the fluids from the primary inflamed part, are the chief causes of it, in connection with weak powers of resistance; but when a part opposite to, or adjoining, an inflamed surface also becomes inflamed, without the intervals between both being affected, the cause will generally be found to have been the fluids effused from the part first inflamed, which have acted as excitants or irritants of the healthy parts with which they have come in contact. Inflammations of serous, cutaneous, and mucous tissues frequently illustrate this fact. When distant parts are secondarily affected without admitting of this explanation, we can only infer that, as long as constitutional disease exists, so long will it continue to manifest itself locally or externally, or in some part or other of the same tissue which it is most disposed to affect, or in some other predisposed part.

115. *b*. In several asthenic, specific, and chronic states of inflammation, the morbid matter absorbed from the primary seat of disease inflames chiefly either the *absorbents* or the *glands*, or both the *lymphatics and glands*; the former often in their whole course, from the primary lesion till the glands are reached, the latter principally in the groins, arm-pits, and neck.—In either case, the connecting and surrounding cellular tissue is also inflamed, small abscesses are formed, or a diffused infiltration of a sero-puriform, sanious, or ichorous matter takes place in their vicinity, especially around the glands; and the disease is thus complicated and prolonged. The constitutional powers in these cases, are affected more and more seriously, owing to the effect produced either upon the organic nervous influence, or upon the vascular system and blood itself, or to these causes combined; but the local, and especially the general, disease presents characters having more or less reference to the primary or exciting cause, from which indeed it derives its specific characters, as when inflammations are caused by a specific animal poison.

116. *c*. The *veins* are often the seat of the consecutive inflammation, especially after the primary asthenic forms of the disease, or when the powers of life are depressed, — when the fluid products of inflammation are effused upon wounded or divided surfaces, or are insufficiently confined by the effusion of coagulable lymph, or by cysts, — and when morbid secretions remain long in contact with absorbing surfaces, or in situations where venous imbibition may take place, as in the cavity of the uterus after delivery, and on divided surfaces after amputations and other surgical operations. In these cases, the consecutive phlebitis assumes various characters, according to the constitutional powers of the patient. If the vital powers be not materially reduced, coagulable lymph is thrown out upon the internal membrane of the veins, and the blood is thereby coagulated in them. The circulation through them is thus arrested, and the products of inflammation are prevented from mixing with the mass of blood. In such cases, the inflammation sometimes extends to the more external coats of the vein, and small abscesses form externally to them, and press upon and obliterate their canals; the obstruction to the circulation in them thus occasioned, further preventing contamination of the fluids. In other cases, purulent matter is secreted within the vein, and is partially confined either by coagula or by albuminous exudations on the internal surface of the vessel, or by both; and, in some instances, even when these have been formed, the puriform matter has evidently mixed with the blood without coagulating it. When pus has been found in the centre of coagula, it is extremely probable, that it has caused the coagulation of the fibrinous portion of the blood in the partially obstructed vessel, and has thus become inclosed in the coagula. When the powers of life are extremely depressed, the secondary phlebitis is not limited by an effusion within the vessels of coagulable lymph, with or without pure pus, and by an extension of the inflammatory action to the external coats and connecting cellular tissue, as in the above states of the disease, but is rapidly extended along the internal surface of the veins; the morbid secretion from the surface not consisting of coagulable or healthy lymph, or even of pus, but of a sero-puriform or of a sanious or ichorous fluid, which is not capable of coagulating the blood in the inflamed veins, but which readily

mixes with it, and contaminates it, thereby producing all the phenomena of adynamic or malignant fever. (See art. VEINS — *Inflammation of.*)

117. *d.* Inflammations of *parenchymatous or other viscera* are often *secondary or consecutive* upon primary inflammation of remote or external parts. The brain, the lungs, liver, and kidneys are most frequently thus remotely affected. In these cases, there may be extensive inflammatory appearances without purulent collections; but most frequently one or more purulent collections, or distinct abscesses, or merely puriform infiltrations of the inflamed parts, are observed. In some instances, the puriform collections and infiltrations are attended either by very few marks of inflammatory action, or by almost none, so as to render it even doubtful, whether they have resulted from inflammation, or from a simple deposition, or separation, from the capillaries of the secondarily diseased part, of the morbid fluids absorbed into and circulating with the blood. I believe, however, that, in these cases, the morbid matter in the blood excites a sufficient degree of inflammatory irritation of the capillaries of this part, to form the diseased secretion infiltrating it; and that, as in other instances where inflammation has unequivocally existed during life, the principal indications of it, in the affected tissues, have vanished soon after death.

118. When secondary inflammation seizes upon a parenchymatous organ, remote from that primarily affected, it will generally be found that it is owing to the passage of the morbid fluids from the primary seat of inflammation into the blood, these fluids consecutively inflaming the parts most predisposed. In some cases the secondary disease has been preceded by, and is associated with, phlebitis; in others, this complication cannot be detected. Even in cases of primary, as well as of consecutive phlebitis, secondary inflammations of internal viscera, with purulent collections or infiltrations, are very frequent. But this subject is fully discussed in the articles ABSCESS, and VEINS.

119. *e.* Consecutive inflammations of *synovial capsules*, and in *serous surfaces*, are observed chiefly in similar cases and circumstances to those just described (§ 115. 118.), — when the blood contains morbid secretions, or when the veins are inflamed and the powers of life much reduced. The former of these structures are often affected by the contamination of the fluids consequent upon syphilis, and upon the subsidence of confluent small-pox; the latter in the advanced stages of diffusive inflammation of the cellular tissue, or of phlebitis, or of inflammation of the lymphatics, particularly when either disease extends to the trunk. It also is sometimes consequent upon extensive burns or scalds, especially when the surfaces over the large cavities are primarily inflamed by these accidents.

120. *f. Mucous surfaces* are secondarily inflamed, both by the passage of the fluid products of primary inflammation over them, as when laryngitis or bronchitis supervenes upon an ulcerated cavity in the lungs, and by the absorption of these products into the blood. These surfaces, especially those of the large bowels, perform an excreting, as well as a secreting function, and the morbid matters, in the course of their elimination from the circulation, excite inflammatory action, generally of an asthenic form, not only in these surfaces, but also in other organs performing similar offices, as the kidneys, liver, &c. Thus secondary inflammation and ulceration of the large bowels, kidneys, &c., often occur in the course of tubercular excavation and ulceration of the lungs, and of abcesses in the liver.

121. VI. PROGNOSIS.—The prognosis of inflammation can be stated only in general terms. The more special circumstances connected with this subject must necessarily be considered in the articles devoted to the inflammations of particular organs and textures; for the result will mainly depend upon the organ affected, as well as upon the form, severity, and stage of the disease, and upon the consequences which may have already taken place.

122. *A. As to the organ or structure affected*, it is unnecessary to state more than that the danger of inflammations is great in proportion to the vital importance of the affected part. Acute inflammations of the stomach, of the intestines, of the lungs, of the heart, of the brain, of the liver, and of the kidneys, are all attended by more or less risk, owing to the disturbance of function attending them, to the shock which the whole frame experiences from the attack, and to the consequences and changes of structure, or the disorganisation, which they often occasion. Yet the danger is still greater when the *blood-vessels*, whether arteries or veins, are inflamed; for the products of the morbid action are then liable to mix with, and to contaminate, the blood, and thereby to infect, in a very dangerous manner, the whole frame. — Inflammations of *serous membranes*, particularly at advanced stages, and in unhealthy subjects, are always attended by great risk of life; for the fluids effused by the disease either accumulate to a fatal extent in the shut cavities they form, if effusion be not early prevented or restrained, or agglutinate their opposing surfaces, so as to impede the functions of parts and to occasion dangerous consecutive disease. Much, also, of the risk attending inflammation of parenchymatous organs proceeds from the extension of the disease to their serous surfaces, and from the effusion consequent thereon. — Inflammations of *mucous surfaces* are much less dangerous than those already mentioned; and chiefly because the secretions which they produce favour a resolution of the morbid action, and are thrown off the diseased surface, — a source of irritation being thus removed. They often, however, occasion great risk to life, by the extent of surface affected, and by the disturbance of the functions performed by it, as in cases of universal bronchitis, where the changes produced by the air on the blood are impeded both by the disease, and by the morbid secretion produced by it. Inflammation may also extend from these surfaces to adjoining structures; the substance of vital organs, and even their serous envelopes, becoming extensively implicated, and the danger proportionately increased. — The *consecutive*, and particularly the *secondary*, *inflammations* described above (§ 112. 114.) are always most dangerous.

123. *B. The form and severity of the inflammation* necessarily influence the prognosis. — In general the *asthenic forms* are much more dangerous, other circumstances being the same, than the *sthenic*. Yet a very acute sthenic state of the disease, especially of internal viscera, may be as

rapidly fatal as any other, — the intensity of the morbid action soon exhausting vital power, and superinducing the more unfavourable consequences and terminations already described, especially copious effusion, suppuration, gangrene, &c. — The asthenic states of inflammation, even in external and non-vital parts, are seldom devoid of danger, unless they are early subjected to a most judicious treatment; for they generally originate in unfavourable circumstances: either the constitution of the patient is impaired, and the assimilating and excreting functions are weakened; or the causes which produced them are poisonous, contaminating, or infectious. Their diffusive or spreading character, generally arising out of these circumstances, increases the risk, not merely from the extent of the diseased state, that results, but also from the contamination of the circulating fluids that often takes place, and the consequent depression of the powers of life.

124. *C. The age, strength, previous health, diathesis,* and *habits of the patient,* are concerned, not only in favouring the production and the character of the inflammation, but also in modifying its course, consequences, and terminations.—Early age, strength of constitution, and previous good health, are generally favourable circumstances, in respect both of the form and result of the disease. Yet, in very robust and plethoric persons, accustomed to active exercise in the open air, and in the habit of drinking largely of malt or spirituous liquors, inflammation is apt to assume a most intense form, rapidly terminating in gangrene, effusion, or abscess. Inflammations of previously weakened or diseased organs, or of parts which have formerly been the seat of inflammation or congestion, and in the scrofulous, gouty, or rheumatic diathesis, are more or less unfavourable, particularly if affecting internal viscera; and, even in the mildest forms, are managed with great difficulty. — The habits and modes of life of the patient remarkably influence the prognosis. Persons who live temperately and abstemiously, and particularly those who partake of little animal food, and who abstain from stimulating beverages, are seldom subject to severe or dangerous inflammation On the other hand, persons who live grossly, who eat much animal food, and who drink much malt and spirituous liquors, experience the most severe and unfavourable forms of the disease, — especially if they are engaged in sedentary occupations, or take insufficient exercise.

125. *D.* It is obvious that inflammations are more unfavourable in *an advanced stage,* than when they come under treatment at an early period. But the degree of danger will depend chiefly upon the consequences to which they have already given rise, and to the seat and form of, and other circumstances connected with, the attack. The *extent* and exact *condition* of the local affection, and of the *effusion* which has taken place; the extent to which the functions of the affected organ are impeded; the commencement or presence of *suppuration,* or the imminent risk of *abscess;* the state, severity, and character of *the constitutional affection;* the degree of disorder manifested by the digestive, excreting, circulating, and nervous systems; and the state of the vital powers, — must all be taken into account, and an opinion formed conformably with the conditions they severally present: for, in proportion to the progress of the disease, and of any of its consequences, and to the amount of disorder manifested by the constitution generally, or by a vital organ in particular, will the risk of an unfavourable issue be great, especially if an internal viscus be the seat of inflammation. The degree in which the cause of the disease may operate during its continuance, should also influence an opinion as to the result; for it is obvious, that persistence of the causes will increase and prolong the effect, and render the consequences more unfavourable, than when the causes have been removed. (See arts. Abscess, Adhesions, Gangrene, and the articles on diseases of the individual tissues.)

126. VII. Theory or Nature of Inflammation. — The various states of inflammation cannot be satisfactorily considered without reference to the structure and vital relations of the arterial and capillary vessels; and, indeed, of the vascular system generally. — *A.* The *external* or *cellular coat* of arteries is more dense than common cellular tissue; and hence it rarely partakes of the serous infiltration of this tissue. It sometimes, however, is the seat of inflammatory exudations, particularly of coagulable lymph; and it occasionally contains a small quantity of pus, and more rarely of extravasated blood. It possesses the greatest degree of tenacity of any of the coats. — The *middle* or *fibrous* coat is highly elastic, particularly in the circular direction of the fibres, and consists of a substance in all respects resembling the elastic ligament of the spine. The fibres composing this tunic are connected by fine cellular tissue, but are easily separated by the pressure of a ligature. This coat is most developed in the large arterial trunks, and most subject to the impulse of the heart; it almost disappears in the smaller arteries, and entirely in the capillaries. The elastic power which it exerts, keeps up a continued pressure on the column of blood in the arteries; diminishing, however, with their size, until it nearly ceases in the capillaries. This elasticity accommodates the vessels to the quantity of blood passing through them, and facilitates the circulation by the pressure and reaction exerted on their contents. — The *internal* or *membranous coat* is highly polished on its internal surface; is transparent; and, although it resembles the finer serous membranes, it is more friable on pressure, and yet more elastic, than they.

127. In the finer arterial branches and capillary vessels, the fibrous or middle coat of the arteries disappears, so that these vessels seem to consist only of membranous canals, surrounded by cellular tissue. The muscularity and irritability of these vessels, although the subjects of so much discussion from the days of Vacca and Haller, are mere figments, which now deserve not the least notice. The muscularity does not exist, and the irritability is merely simulated by the changes consequent upon the application of agents which affect the organic nervous influence, and vital contractility of the tissues and capillaries.

128. The *nerves* which supply the arteries and capillaries are chiefly ganglial, or derived from the organic or sympathetic system. But filaments from adjacent parts of the cerebro-spinal nervous system communicate with them. Ganglial nerves have been traced around the arteries as far as the interior of the cranium, and the principal arteries

of the extremities, by Weber and the author, in 1816 and 1817, and more recently by Ribes and others; and there can be no doubt that they extend even to the capillaries, endowing these vessels with influence, and with the properties evinced by them in health and disease.

129. The *vital states* which arteries and capillaries manifest, especially when influenced by stimulants, or depressants, are these: — 1st. Of turgescence, dilatation, or enlargement; — 2d. Of contraction or constriction; and, 3d. Of healthy or natural tone. — The first and second are anormal states, the third normal, and consistent with all the natural functions. It is to the *first* of these that attention is principally to be directed in discussing the nature of inflammation; but, before this state is considered, a very few remarks may be offered on the others particularised.

130. *a.* The *constriction* of arteries and capillaries arises chiefly from agents, which increase the vital contractility of tissues. Many of these agents are of very opposite natures, and yet they act, particularly in certain grades of activity, and periods of operation, in definite modes. Cold, fear, and other depressing passions, severe injuries, shocks to the system, &c., contract parts susceptible of organic contractility, especially the skin; arterial, capillary, and venous canals; cellular and serous tissues, &c. &c.: but, if the operation of these agents is intense, or long continued, the natural tone of the contractile tissues and vessels is impaired, and vital exhaustion or relaxation ensues. A similar constriction of these parts follows the application of astringents and refrigerants; the sudden diminution of the circulating fluids, as by hæmorrhage or venæsection; and the depression of vital power by whatever cause. The contraction of arteries and capillaries soon after death depends chiefly upon the weakened injection of blood into these vessels, just before dissolution, and to the entire cessation of the action of the left ventricle. The organic or vital contractility of arteries and capillaries is then no longer antagonised by the action of the ventricles upon the column of blood they contain, and is consequently allowed to advance to the utmost permitted by the fibrous and cellular coats; the arteries, and even the capillaries, being consequently found nearly empty and constricted after death. But as contractile parts lose their rigidity or tone with the incipient decomposition of the structures, the vessels afterwards relax, so as to allow a larger column of fluid to be injected through them than in the living state.

131. *b.* In the *healthy* or *natural tone* of contractile tissues, the arteries, capillaries, and even the veins, fully participate. Still this natural state of the vessels is liable to various deviations or deflexions, either to the side of turgescence, or to that of constriction, without amounting to what constitutes a truly morbid condition. Numerous causes produce either constriction or turgescence, without reaching the pitch truly injurious. It is chiefly when the action of the causes is intense or continued; or when they alter, by their primary and specific influence, the vital properties of the sentient system and contractile tissues; that the effect becomes truly morbid, and diseased action is set up. Much, however, depends, in such cases, upon constitutional disposition, or the degree and kind of susceptibility existing at the time of exposure to the causes. Agents which produce no derangement in some persons, violently affect others; and the same cause, which was without effect at one time, may be most injurious at another, — owing to varying states of organic nervous energy and susceptibility.

132. *c.* The *state of turgescence, dilatation*, or *enlargement* of the smaller arteries and capillaries, although a part of the inflammatory act, does not alone constitute it. Something more is necessary to its unequivocal production. This state may take place without being at all morbid, — as in the excitement of erectile parts, in the development of the uterus and mammæ during pregnancy, in the enlargement of collateral vessels after the obstruction of a large artery, in the act of blushing, and in the rapid growth or restoration of parts. It may even be morbid, or at least the source of disorder, without constituting inflammation. The active congestions and determinations of blood to particular organs, although often passing into inflammation, yet are very different from it. In these vascular disorders, more or less turgescence, or dilatation, of the smaller arteries and capillaries, as well as of the smaller veins, obviously exists; but still this state is not attended by the same phenomena, and does not give rise to the same consequences, as are observed in the various forms of inflammation. This state of turgescence of the capillaries of inflamed tissues has especially fixed the attention of modern pathologists; and the question, with them, has been almost limited to the inquiry, as to whether the increased diameter of the capillaries is to be imputed to relaxation or debility, or to augmented action. The least material point of the many, which should have fixed their attention, has thus alone engaged the whole of it; and, whilst they have attributed every thing to one or other of these two conditions, they have entirely overlooked the fact, that they are both contingent or consecutive changes; that either may exist according to the stage and form of the morbid action; and that the one as well as the other may be present quite independently of, and without, inflammatory action.

133. The *state of the capillary circulation* in inflammation has been agitated since the commencement of the present century, and even at the present day, with a parade of useless, deceptive, and ill-conducted inquiry, dignified with the name of experiment. Numerous cold-blooded and other reptiles, and often animals, very differently organised from the higher species, have been tortured for evidence, whereupon an argument might be hung in behalf of preconceived hypotheses; and crude and puerile observations have been made the basis of doctrines, which have failed of attracting notice, either from having been imperfectly understood, even by their propounders, or from having been overlaid by the multitude of words, in which attempts have been made to convey them. Thus the author of a recent work, entitled "A Critical and Experimental Essay on the Circulation of the Blood," &c., not only derives his inferences from imperfect observations, made at similar sources to the above, but also, because he observed an oscillating motion of the blood in the aorta of a frog after tying the vessel, jumps to the conclusion that, "it would appear almost certain that the arteries

possess a muscular contractile power;" although the previous inquiry, as to the existence of a muscular structure in the coats of these vessels, that some honest observers might, perhaps, have thought necessary, had never been entered upon by the author.

> "Such reasoning falls like an inverted cone,
> Wanting its proper base to stand upon."

134. Before entering upon a fuller explanation of my own views as to the theory of inflammation, and which are essentially the same as were published at first, more than twenty years ago, and at several times subsequently, the opinions of some writers most deserving notice may be adduced; although, as respects inflammation especially, a rational explanation of phenomena, as they are subject to our senses, is to be preferred to a mere collection of opinions — of hypotheses; in many of which, parts only of the truth appear — the rest being either kept entirely out of view, or hid under an accumulation of loose analogies and inconsequent argument, or buried in heaps of unmeaning verbiage.

135. i. Opinions as to the Nature of Inflammation. — *A.* Inflammation was very generally attributed to vitiated states of the fluids, until Van Helmont ascribed it to an irritation which attracted the blood in a greater quantity than natural into the capillary vessels, — the irritation arising from an affection of the *archæus* or vital principle. Willis, notwithstanding his espousal of the chemical doctrine of the blood, attributed more to the local irritation of Van Helmont, in the production of inflammation, than to the morbid condition of this fluid. Towards the close of the seventeenth century, several theories of inflammation, and of disease in general, were promulgated. The followers of Des Cartes imputed inflammatory action to a fermentation excited by the æthereal fluid which they supposed the blood to contain, and which Des Cartes substituted for the *gas*[*] of Van Helmont. The opinions of Sylvius were merely modifications of those of the two pathologists just named, and an accommodation of them to the chemical doctrines of the day — acidity of the fluids performing an important part in his theory. Le Mort, Schneller, (*Theoriæ Mechanicæ Delineatio*, 8vo. Leyd. 1705.) and others, adopted the mechanical parts of the doctrines of Des Cartes, and associated them with certain chemical hypotheses not much more deserving of notice. They imputed inflammation to irritation caused by the æthereal particles of the fluids without any reference to other changes. The partial rays of light, furnished by the rising of chemical science in Europe, were soon employed to explain morbid actions; but they led, especially at first, to little more than to modifications of the doctrines previously adopted, and particularly of the humoral pathology, and never disclosed results deserving of lasting attention.[†]

136. Pitcairn, the master of Boerhaave, first opposed the chemical pathology then very generally received, and applied the mathematical doctrines promulgated in Italy by Borelli, Sanctorius, and Bellini, and still more widely disseminated by the classical work of Donzellini (*De Usu Mathemat. in Arte Medica: in Guilielmini Opera.* 4to. Genev. 1719. t. ii. p. 516.), to the pathology of inflammation. To those acquainted with the physiological and pathological views of Des Cartes, the mathematical doctrines of the Italian physicians will appear as a very obvious and easy application of mathematics to the mechanical parts of the pathology, of which this philosopher may be said to have been the founder. Although numerous modifications of the theory of inflammation were proposed by writers of the mathematical school, yet they may be generally referred to an *error loci*, or to the obstruction which they supposed to be occasioned by the passage of the larger sized globules of the blood into a smaller series of capillaries, intervening between the arteries and veins[‡], than are destined to receive them.

137. Boerhaave proposed a theory, which, if it was not altogether original, was at least an important modification of that of Pitcairn, and of the mathematical school. He supposed that the blood itself became more viscid, causing a *lentor* in its circulation through the several orders of capillary vessels, and an excessive engorgement of them; an increased action of the larger vessels, and flow of blood in them, taking place to overcome the resistance and congestion. The close resemblance of this hypothesis to others much more recently proposed, is very obvious. That the action of the larger arteries should be increased, where an obstruction to the circulation through the capillaries exists, may readily be conceded; but that the afflux of blood can be increased, and obstruction at the same time exist, is a contradiction in terms. In one essential point connected with the theory of inflammation, Boerhaave differed altogether from Pitcairn. The former supposed that a constriction of the

---

[*] Carbonic acid and hydrogenous gases were partially known to Van Helmont, and this imperfect knowledge of gaseous fluids became the basis of several of his pathological views.

[†] The Dutch physicians at the end of the seventeenth century were amongst the chief writers on Pathology, and consequently on Inflammation; and the schools of medicine in Holland were acquiring a reputation, which rose with the commercial prosperity of that country. But it is not altogether uninteresting to remark how many of the medical writers in it, about this time, adapted their pathological views, as well as their practical precepts, to the promotion of the traffic of the people. The foreign trade of Holland, rising upon the decay of that of Portugal, Spain, Venice, and Genoa, furnished numerous articles of luxury, not only to the Low Countries, but also to all Germany, and the East of Europe. Many of the medical writers of the country brought them into general use; and, whether they imputed inflammation and other diseases to inspissation, or to acidity, or to alcalinity, or even to effervesence, of the circulating fluids, still tea, tobacco, coffee, and opium, in extraordinary quantities, were not only the chief remedies, but also the principal prophylactics recommended by them.

[‡] The mathematical school boasts of a numerous list of names eminent not only in medical, but also in mathematical, science and in art — of Guilielmini, Michelotti, Bernouilli, Baglivi, Perrault, Chirac, Quesnay, Hales, Mead, Sauvages, and others; and furnishes many splendid examples of the dignity, as well as of the aid, which general science has imparted to the study and practice of medicine. The mathematical doctrine of inflammation was founded on the belief, that the globules of the blood consisted of various sizes, and that the red globule was formed of six serous globules, and each serous, of six lymphatic globules; three orders of capillary vessels, suited to the conveyance of these globules existing between the arteries and veins. The obstruction caused by the passage of red globules into the wrong order of vessels constituted what they termed an *error loci*, and the cause of inflammation. — Whilst the Cartesians insisted much on the various forms of the globules and pores, the mathematicians contended chiefly for the different sizes of the globules and capillaries.

capillaries caused a congestion of blood and slower rate of circulation, whilst the latter considered that an increased diameter of the vessels had this effect. The great defects in the opinions of these physicians, independently of their incorrect views as to the conformation of the capillaries, and as to the constitution of the blood and blood-globules, were their entirely leaving out of consideration the power exerted by the organic nervous or vital influence upon the vessels, and upon the circulation through them; and their being unaware of the fact, that both constricted and enlarged capillaries, or other vessels, may have the circulation through them either accelerated or retarded, according to the state of that influence by which the capillaries, and tissues in which they ramify, are actuated.

138. Whilst the mathematical theory of inflammation and disease was evidently supported by, if it did not originate in, the philosophy of Newton, and was the first manifestation of the comparatively modern doctrines of solidism, the views of Hoffmann were more referrible to the system of Leibnitz, and a more complete adoption of the influence of the soft solids in the production of morbid actions. According to this celebrated pathologist, inflammation proceeds from spasm of the smaller vessels, which suspends or impedes the circulation in one part, and determines it inordinately to others, red blood being thereby propelled into capillaries, which in other circumstances admit only the serous portion of it; pain, swelling, and heat resulting therefrom. This theory soon found supporters; and, notwithstanding the already promulgated doctrines of his contemporary and colleague Stahl, these soon became numerous. Whilst the doctrines of Stahl and Hoffmann were dividing the schools of Germany, and especially that of Halle, where they were taught by these celebrated professors, the opinions of the mathematical pathologists and of Boerhaave were predominant in this country and in Scotland, until the lectures and writings of the elder Monro, of Whytt, and of Cullen, attracted notice.

139. The medical doctrines advanced in Germany at the close of the seventeenth, and at the commencement of the eighteenth, centuries, had more or less reference to the most generally received metaphysical views. The relations already noticed between the doctrines of inflammation hitherto adopted, and the pathology of Des Cartes, existed chiefly in respect of their more mechanical parts. But the psychological opinions of Des Cartes, and of his successor Malebranche, were not made the basis of a system of pathology until Stahl adopted them as such at a very early period of life. Perrault* had previously demonstrated the influence of mind upon all the bodily functions; but Stahl had reference to this influence in the production, not merely of inflammation, but also of all diseases, notwithstanding the objections of Gassendi, urged against the physiology of Des Cartes, that the direct influence of the mind was limited to the brain and the organs of sense and volition.

140. The doctrines of Stahl and Hoffmann continued for many years to divide medical opinion, notwithstanding the efforts of Kaauw Boerhaave in behalf of the views of his more celebrated uncle, and his endeavours to connect them with the system of Hoffmann. In this country the opinions of Hoffmann, according to the explanation and modifications of them attempted by Cullen, became most generally adopted, particularly with reference to inflammatory diseases, although the able writings of Whytt strictly belonged to the school of Stahl. Of all the successors of Boerhaave, Gorter most strenuously insisted upon the fact, that inflammation does not consist of congestion of the diseased part, but of an irritation affecting the vital condition of the vessels; and the circulation in them. The influence of irritants upon the state of vital action was, however, first contended for by Glisson; but to Gorter and Gaubius belongs the credit of having more fully illustrated it, and developed the laws of excitement, thereby furnishing a basis for the doctrines of Brown and Darwin at a much more recent period.

141. Whilst the doctrines of Boerhaave, Stahl, and Hoffmann were dividing medical opinion, and at a time when the views of Hoffmann were gaining the ascendancy in their more general adoption, Haller first published his opinions on *irritability*. He afterwards developed them more fully, and referred this property to the organisation of the muscular fibre, but was opposed by Whytt, Lorry, and Gaubius, as to its precise source; and, contrary to the opinion of the former, who referred irritability to cerebro-spinal nervous influence, he carefully distinguished it from, and endeavoured to prove its independence of, this influence. He disputed the doctrine of this pathologist, that exaltation of irritability determines the circulating fluids to inflamed parts; yet there is no doubt, as Whytt observes, that the "heat, redness, and inflammation, brought on the skin by blisters and sinapisms, are not owing to any increase of the force of the heart, or of the *momentum* of the blood in the larger vessels, — though this is often an effect of their application,—but merely to the action of these irritating substances on the cutaneous vessels, whereby the motion of the fluids in them is greatly augmented." Haller believed that the accumulation of blood in the capillaries was owing chiefly to constriction of the small veins, and that the derivation of this fluid to any particular part should be attributed to the removal of the resistance furnished by the state of the capillaries and veins. He agreed with Whytt, that obstruction cannot of itself produce inflammation; and insisted upon extravasation of the red particles, as constituting a part of the redness observed in some inflamed tissues. Winter, nearly at the same time as Haller, published views as to irritability, similar to those of this celebrated pathologist; and Verschuir greatly extended, and at the same time modified, the doctrines of the latter, especially as to irritability of the arteries and capillaries in warm and cold-blooded animals. The

* Perrault commenced his magnificent career as a physician, and soon acquired by his writings the first eminence as a physiologist, naturalist, painter, sculptor, mechanist, and architect; in which last character he is best known, especially as the architect of the beautiful façade of the Louvre. He translated and illustrated Vitruvius with splendid drawings and engravings; wrote an extensive work, in two folio volumes, on the Natural History of Animals; published numerous Essays on Physiology and Physics; and at his death left for publication a collection of recently invented and useful machines. All his writings abound in originality; for, in his very diversified studies, he was guided chiefly by observation and his own genius.

chief sources of error in the observations of those eminent writers are their having viewed the fibrous coat of the arteries as muscular; their imputing the properties of muscular tissues, not only to these vessels, but also to the capillaries, which are unprovided with this coat; and their confounding not only organic or insensible contractility and vital expansion, but also the elasticity of fibrous tissues, with the irritability or sensible contractility of muscular fibres. The intimate structure of parts, and the kind and degree of vital manifestation proper to each, were imperfectly known to them, and indeed to many of their successors, and were insufficiently distinguished one from another; and hence were confounded in such a manner as to vitiate most of their pathological inferences.

142. The chief modification in the theory of Hoffmann, suggested by Cullen, was his belief in a *phlogistic diathesis*, predisposing to, and occasioned by, local inflammation, — this diathesis consisting in an increased contractility of the fibres of the whole arterial system. He objected to the opinion of Boerhaave, as to congestion of the vessels being a part of the inflammatory state; and contended that the obstruction is owing to spasm, which indirectly causes an increased afflux of blood to the affected part. "A spasm," he remarks, "of the extreme arteries, supporting an increased action in the course of them, may therefore be considered as the proximate cause of inflammation, at least in all cases not arising from direct stimuli applied; and even in this case, the stimuli may be supposed to produce a spasm of the extreme vessels."

143. Some pathologists, towards the close of the last century, and in still more recent times, being unable to reconcile the idea of increased action with the enlargement of the capillaries, and the swelling constituting inflammation, believing, as they did, that increased action must necessarily be productive of contraction, had recourse to the supposition that the disease depended upon *relaxation and diminished action of the extreme vessels;* others, again, ascribed inflammation to *increased action of these vessels;* and thus pathologists were divided into two opposing parties. The chief fallacies, common to both, were, their having taken it for granted that capillary and arterial vessels possess a muscular structure performing the function of muscular parts; and that an increased action, according to the one party, and a diminished action, according to the other, constitutes the principal, and indeed the only, morbid condition throughout the disease. These opposite doctrines have been so warmly discussed in recent times, each party endeavouring to support their own views by experiments, that it becomes necessary to consider them somewhat in detail.

144. *B.* The *doctrine of relaxation*, or diminished action of the capillaries in inflammation, the blood becoming nearly stagnant in the dilated vessels, originated with Vacca Berlinghieri (*De Inflam. Morbosæ Naturâ, Causis, Effectibus, &c.* Flor. 1765.), and was promulgated in this country by Mr. Allen, who modified the opinion of Vacca, and contended that the action of the arteries is increased, a larger quantity of blood being thereby propelled into the weakened capillaries than they can transmit. According to this theory, the exciting causes, even when they stimulate the part, produce not an increased action of the capillaries, but only excite the larger arteries supplying the inflamed structures, and ultimately quicken the contractions of the heart. The effect of this is, that a larger quantity of blood than usual is propelled into the weakened capillaries, and especially the colourless branches; and upon this unusual quantity the weakened vessels are unable to react, so as to carry on the circulation — stagnation and obstruction in them being the result. Dr. Wilson Philip modified the doctrine of Vacca in a different manner; and, whilst he maintained that the extreme vessels are primarily weakened, he contended that the action of the larger arteries supplying these vessels is consecutively increased; the differences between active and passive inflammations depending, according to him, upon the degree in which the arteries supplying the blood to the inflamed part are excited. In further illustration of his views, by experiments and microscopic observation, Dr. Philip remarks, that "the motion of the blood is retarded in the capillaries, in consequence of the debility induced in them: an unusual obstacle is thus opposed to its motion in the arteries preceding them in the course of the circulation, which are thus excited to increased action." In this statement of his views, one difficulty presents itself: — How comes the debility of the capillaries, causing retardation of the motion of the blood through them, to follow directly upon the application of stimuli? Dr. Philip infers the debility from the apparent retardation of the circulation of the red globules in his microscopic experiments; and, having inferred the debility, concludes that the apparent stagnation must really exist. Thus reasoning in a circle, he states the above doctrine as its result. The difficulty here adverted to, seems not to have escaped Dr. Hastings, who appeared in support of the opinions of Dr. W. Philip. The experiments of Dr. J. Thomson, stated in his excellent work on Inflammation, had demonstrated certain points subversive of the doctrine of Dr. Philip, and of these Dr. Hastings took some notice. Inferring, with his master, or, more correctly, with Vacca Berlinghieri, that "inflammation consists of a weakened action of the capillaries, by which the equilibrium between the larger and smaller vessels is destroyed, and the latter become distended," he, nevertheless, is compelled to admit, that increased action or temporary excitement of the capillaries may precede the debility constituting inflammation. "Certain stimuli," he remarks, "applied to living parts, produce an increased velocity of the blood's motion, and a contraction of the vessels. During this state of excitement, the part affected is so far from having any thing like the appearance of inflammation, that the size of the vessels is diminished, and the part paler. But if the stimulus be long continued or increased in power, the small vessels, which, in the natural state, admit only of one series of globules, become so dilated as to allow an accumulation of a much less fluid and redder blood in them, which loses its globular appearance, and moves much more slowly than that which previously passed through the vessels. The part now appears inflamed. If the stimulus be removed, the blood-vessels do not soon regain their original state; time is necessary to allow them to recover their contractile power, so as to prevent the impetus with which the blood is propelled by the heart and larger arteries from keep-

ing up the dilated state of the capillaries." Dr. HASTINGS further contends, that, when acrid substances produce inflammation, debility of the capillaries takes place without previous excitement, the blood becoming very red, circulating very slowly, and stagnating in some of the branches. As Mr. MORGAN remarks, the hypothesis of weakened action of the capillaries, and slower motion of the blood in them, has been the most generally adopted of the recent theories of inflammation, because it admits of a more easy demonstration with the microscope.

145. All the supporters of this doctrine err, in attributing little or no share in the inflammatory act to direct excitement of the capillaries,—in believing that excitement must necessarily be attended by constriction of these vessels, and that dilatation of them is incompatible with increased vital action,—and in dismissing from their consideration the other morbid acts contributing to the production of the disease in its various stages and forms. That the extreme capillaries are weakened, dilated, and congested, and even that the blood stagnates in them at a more or less advanced period of sthenic inflammations, and at a very early period of the asthenic forms, have been stated above; but this condition is only one of several constituting the disease, which, in no instance and in no stage, depends upon a singleness of event, as contended for by the espousers of this and the opposite theory.

146. *C*. The *doctrine of increased action* of the vessels in an inflamed part may be attributed, as stated above (§ 140.), to GORTER and GAUBIUS, if not to GLISSON. They considered that inflammation was the consequence of *irritation*, which increases the vital action of the vessels, and propels the coloured blood into the colourless capillaries. Mr. J. HUNTER believed that inflammation is an increased action of the vessels of a part, attended by accelerated circulation; but he erred in supposing the vessels to be muscular, and the error vitiates more or less all his reasoning on the nature of the disease. Mr. MORGAN states that Mr. HUNTER's "opinion of the nature of inflammatory action is not clearly stated, nor does it appear from his writings that he had ever made any experiments in order to ascertain the state of the minute vessels." Mr. HUNTER, however, has stated his opinion of the nature of inflammation in several places, even in the same chapter, and to the purport just given. At another place he observes, "the very first act of the vessels, where the stimulus which excites inflammation is applied, is, I believe, exactly similar to a blush. It is simply an increase or distension beyond their natural size;"—and again, "whatever purpose the increase of the size of the vessels may answer, we must suppose that it allows a greater quantity of blood to pass through the inflamed part than in the natural state, which supposition is supported by many other observations." Indeed, the whole of the section, on the "*Action of the Vessels in Inflammation*," contains a very detailed and distinct account of his views as to the nature of the disease. As to the assertion, that Mr. HUNTER never made experiments to determine the nature of inflammation, the reader has only to refer to the section just mentioned, where he will find the details of observations and experiments made upon warm-blooded animals—not frogs, and other animals unsuited to the satisfactory elucidation of the subject—proving the justness of his views as respects certain states and stages of the disease.

147. The increased action of the capillaries in inflammation has been advocated by Dr. PARRY, partly by Dr. J. THOMSON, and by Mr. JAMES. Yet most of the same fallacies which vitiate the doctrine of the opposite party, may be urged against the majority of those who contend for the truth of this, and especially their belief in the irritability of these vessels. Indeed, this phrase has been employed by many, without attaching any precise meaning to it, and without being aware that, if by *increased action* they meant *increased contraction*, or even an increased power of alternate relaxation and contraction, as in muscular tissues, the circulation of the inflamed part would be altered by it very differently from what is actually observed. The circulation in health through the capillary vessels does not require the aid of any action on their part; for the contractions and dilatations of the heart, and the elasticity of the larger arteries, are quite sufficient for the transmission of the blood; not only in the capillaries, but also in the veins. Agents which change the tonicity of the tissues will necessarily affect that of the extreme vessels, and, consequently, the state of circulation through them; but such agents will seldom give rise to inflammation, unless by a succession of changes, of which alteration of the state of circulation,—whether increased or diminished,—is only a part, as I shall endeavour to show hereafter.

148. The experiments which have been planned and performed with a view of establishing the truth of either of these doctrines of inflammation, have been altogether vitiated by the circumstance of the chemical action—1st, upon the tissues,—2dly, upon the capillaries,—and 3dly, upon the blood, of the agents employed in these experiments, having been entirely overlooked. But this is not all; the physiological or vital action of these agents has been neglected, equally with the chemical action, and even with the changes they produce upon dead animal matter. These experiments abound, moreover, in other sources of fallacy, attributable to the means and aids used in ascertaining the effects, and to the subjects upon which they have been performed. Can it be believed that all these circumstances,—any one of which is sufficient to overturn the conclusions drawn from these experiments,—have been neglected? Instead of observing closely the changes taking place in tissues actually inflamed, and the succession of these changes in the different stages and forms of inflammation, as affecting different structures, substances producing both vital and chemical alterations in the tissues, blood-vessels, and blood itself, have been applied to parts, and the effects directly and remotely produced by them have been described as identical with inflammation, and made the basis of the prevailing doctrines of the disease. Before any inference, or even the smallest fraction of information, can be derived from the experiments paraded by many of the writers on this branch of pathology, it is necessary to bear in mind that acids, or alkalies, or alcohol, or turpentine, or neutral salts, when applied to a vascular tissue, produce effects which are not identical with any of the usual forms of inflammation. Acids affect the nervous influence of the part; constringe, corrugate, or cornufy the tissues and capil-

laries; change the colour and state of the blood in the extreme vessels, and arrest the circulation in them; and if inflammatory appearances supervene, much of the primary changes will still continue to modify its characters. Alkalies produce opposite effects; — they weaken the vital cohesion of the tissues, partially dissolve them and combine with them, redden and otherwise affect the blood, and, according to their strength, influence the form and termination of the morbid changes they produce in the part. Turpentine, and, in a less degree, alcohol, in their primary action, change the state of nervous power, constringe the capillaries and tissues, and retard the circulation in them; and neutral salts variously affect the vitality, the structure, the circulation, and the blood of a part, according to their individual constitution. When any one of the numerous substances which may produce inflammation is applied to a living tissue, the effects are not limited to the spot with which it is in actual contact. The impression extends, and a modified, or even opposite, action may be superinduced in surrounding parts. If the substance be injurious, or subversive of vital power in the part, more or less resistance is offered to the extension of the mischief. The injury affects the state of organic nervous power; and the irritation, or consequent reaction of this power, and its influence upon the surrounding vessels and blood, give rise to inflammatory action, either in the seat of injury or around it. If a living membranous tissue be pricked with a red-hot needle, the following effects will result; but these effects, although inflammatory in many respects, are not to be viewed as identical with idiopathic inflammation, as they have been by some writers, and for the reasons which will be stated. The red-hot needle will produce much pain, attended by the immediate constriction or corrugation of the tissues and capillaries; the blood being driven from the part immediately surrounding the puncture, the red globules undergoing a change in colour, and becoming stagnant in, and adhering to, the vessels adjoining the punctured spot. This is the immediate effect; but in a short time, — varying, however, with circumstances, — the punctured spot either becomes dark or black at a central point, around which the vessels dilate, the injury having either destroyed their continuity or obstructed them. The increased vascularity, which soon takes place around the injured spot, now becomes inflammatory, and is partly owing to obstruction in this spot, and to the consequent development of the surrounding capillaries, so as to carry on the circulation. But the affection, by the injury, of the organic nervous influence of the part, so influences the state of the extreme vessels, as to produce the chief of the phenomena. Now the early part of the changes here observed, are not to be viewed as identical with idiopathic inflammation, although illustrative of the production of inflammatory action by certain injuries; for the agent employed cornufies the capillaries, stagnates and changes the blood in them, obstructs their circulation, and severely affects the nervous influence; this last change especially producing, in the extreme vessels of the injured part, consecutive effects, which only are truly inflammatory, particularly in previously healthy constitutions or structures.

149. In order to arrive at any thing like a just notion of the nature of inflammation, the phenomena constituting it should be closely examined from the commencement, whether arising spontaneously, or produced by an irritant or excitant. But the phenomena observed in a single tissue, or in a particular form of the disease, are not to be viewed as constituting alone its characters in all stages, forms, and circumstances. The essential characters, as well as the subordinate phenomena, of inflammation, vary in all the states and stages of it; they are continually changing with their duration and the nature of the causes which produced them, and according to the temperament, habit of body, diathesis, and constitutional powers of the patient. So diversified do they thus become, that it would be endless, if not impossible, to describe them in all their conditions, periods, and consequences. The most prominent pathological states can only be mentioned; the descriptions already given, and the observation or experience of the reader, will supply deficiencies which must still remain, even after the most minute details.

150. ii. Pathology of Inflammation. — *A. Of the Nature of the Sthenic Forms.* — *a. The organic nervous tissue is primarily affected in the seat of inflammations of all kinds.* — I have already contended that inflammation, in its more *sthenic forms*, is a result of a *morbidly* excited state of the organic nervous tissue surrounding the extreme vessels or capillaries of the affected part, or a derangement from an unnaturally exalted condition of these nerves, on which the function of these vessels, and indeed of the whole vascular system, have been shown to depend. One of the chief inquiries concerning the nature* and pathological relations of inflammation is, whether this excited or exalted state of the organic nervous tissue is one of simple excitement or not, — whether the functions of the nervous tissue be merely increased above the healthy pitch, — or whether or not they are also otherwise changed. I have stated them to be morbidly or unnaturally excited, thereby indicating that they are increased differently from what we observe in a healthy part from the application of a stimulus, as respects both the *duration* and the *kind* of action they occasion.

---

* The views which I now proceed to state, were published by me first, as already noticed, in 1815; on several occasions during the years 1821 and 1822, in the *Medical and Physical Journal*, and in the *London Medical Repository*; and still more fully in my *Appendix* to M. Richerand's *Elements of Physiology*, published in 1824. They were the result of a close investigation of the subject; and if the reader will refer to the section on *Inflammation*, which I added to the last of the works just mentioned, and afterwards to that of Kaltenbrunner, published in 1826, he will find my doctrine and observations fully confirmed by his researches, as well as by those of M. Gendrin, also published in 1826. A very large reprint of my *Appendix*, containing the same section on *Inflammation*, without any alteration or addition, appeared in 1829. In 1835, and at still later periods, treatises and essays on Inflammation have been published by several writers, in which the principal parts of my doctrine have been adopted, but without any reference to the original propounder of them. Of this I thought it not worth while to take any notice at the time, as I was about having it in my power to do myself full justice, and to an extent, in respect of circulation, infinitely beyond what could be reached by the works in question. It is very probable that the opinions first brought forward by me have been subsequently suggested to these writers, without having ever perused any of my writings on the subject; yet one of the works only, and that one containing a full exposition of my doctrine, has been circulated to the extent of several thousands.

151. The *duration* of the healthy exalted action consequent upon simple excitement, mental or physical, is generally brief — the effects soon subsiding with the removal of the cause — because the nervous influence exerted on the capillaries is simply increased, without the mode or habitude of this influence being changed in kind. When, however, an irritant, stimulus, or other cause, operates upon a part so as to change the mode of organic nervous influence endowing it and its capillaries, the consequent vascular excitement or action is not only of longer duration, but is also altered in kind: it becomes truly morbid; and it either subsides gradually before the conservative powers of this influence as exerted throughout the frame, or undergoes a succession of changes, until it terminates in one or other of the ways described as usually observed in sthenic inflammations.

152. That the first change occasioned by the exciting cause takes place in the organic nervous influence of the part, is proved by the early effect produced by it upon the organic sensibility, and on the functions more immediately dependent upon this influence. The uneasy sensation of inflammation, in its various states and modes, is to be ascribed (§ 8.) to the morbid impression made on the organic or ganglial nervous tissue, and is to be viewed as the sensible expression of the consequent change in the condition of the influence exerted by this tissue in the affected part, — as indicating a morbid state of this portion of the nervous system, producing, and attended by, deranged action of the capillaries in the affected organ, and often exciting, or otherwise disturbing, the sensibility and functions of the cerebro-spinal nerves, with the terminations of which the former becomes associated in many of the textures. The pain or uneasy sensation attending the changes in the organic nervous tissue, which affect the state of the capillary circulation, so as to give rise to inflammation, is, as shown above (§ 82.), very distinct from the morbid sensibility often manifested by the cerebro-spinal ramifications, as in the different forms of neuralgia, and of spasmodic affection; and, although the latter is much more acute and violent than the former, yet it never gives rise to much vascular disorder. Excitement of the cerebro-spinal nerves has but little immediate influence upon the capillary circulation, excepting that of the countenance, as in the act of blushing; and then this is only temporary. Whatever influence these nerves may possess over the circulation, is only produced through the medium of the organic or ganglial nervous tissue distributed to the capillaries and structures generally. This provision is important as respects the preservation of the healthy functions of parts; for if the vascular system were *directly* under the dominion of the cerebro-spinal nervous system, all the functions of circulation, secretion, nutrition, &c., which are subjected to the organic nervous influence, would be liable to continual derangement from the various impulses of the will and the passions. — From this it will appear manifest, that changes in the cerebro-spinal nerves of an organ, or part, can have but little effect in the production of inflammation, whilst alterations of the organic nervous influence or sensibility are almost, if not altogether, necessary to its existence. In cases of severe injury to the spinal chord causing paraplegia, the lower extremities are not more liable to inflammation than in health.

153. *b. The causes being of an exciting nature, the primary effect on the organic nervous influence, and on the capillary circulation, will partly or chiefly consist of excitement, — the sthenic states of inflammation generally resulting.* — Whenever the causes of inflammation, either directly or indirectly, are of an exciting kind, — whenever excitement is even one only of the effects produced by them, — we must admit that the vital influence of the organic nervous tissue of the part upon which these causes act, will be increased for a time by them; the excitement being, however, modified by their nature. The organic nervous tissue, supplying the capillary vessels of the affected organ, will especially manifest this effect in the altered action of these vessels. Whenever the organic nervous influence is locally increased, the vital actions of the associated capillary vessels are also augmented — the diameter of these vessels becoming enlarged, and a larger column of blood circulating in them with increased velocity. This is evinced during excitation of secreting surfaces and of erectile parts, and by the enlargement of the nerves and blood-vessels of the uterus after impregnation. That the principal part of the more direct effects produced by the application of stimulants to living structures consists of exaltation or excitement of the organic nervous tissue, causing increased action of the vessels, is proved also by the phenomena observed to follow such applications to organs or parts supplied either chiefly or only by organic or ganglial nerves. Now, if we admit, what cannot be disproved, that excitement of the organic nervous influence of a part increases the vascular activity and circulation of that part, it must necessarily follow that, whenever an increase in degree forms a part of the change induced in this influence by the causes of inflammation, a proportionate augmentation of the size of the capillaries will take place — an active expansion, or turgescence, of the extreme vessels will result, and give rise to states of inflammation of a more or less sthenic character, according to concomitant circumstances, either extrinsic or intrinsic, in respect of the peson affected. But that the causes of sthenic inflammations do not merely excite the susceptible nervous tissue, and consequently vascular action, but also otherwise change the former, and consecutively the latter, is proved by the duration of the resulting effects, and by the succession of alterations, both local and general, as above described.

154. *c. In sthenic inflammations, organic nervous influence, and vascular action, are not only primarily increased, but also otherwise changed.* — In the early stage of all inflammations, there is every reason to suppose that the organic nervous influence of the capillaries and inflamed part is not merely changed in degree, but that it is also modified in kind; and that the differences existing, not only in the forms and varieties, but also in the stages, of inflammation, depend upon the extent and combination of these changes, — an excited, and at the same time a modified, kind of influence especially characterising the sthenic forms of this disease; the combination of impaired and altered influence with excited action constituting the more active states of the asthenic varieties. The irritant or other cause of inflammation

seems to impress the organic or vital influence, or the ganglial nervous tissue, of the part, or of the system more generally, in such a manner as to prevent this influence, and the vascular disorder produced by it, from returning to the natural state, at least for a considerable time. Morbidly excited action is thus induced in the capillaries of a part, particularly in the sthenic forms of the disease, and is succeeded by other changes. When the exciting cause alters the organic nervous influence in other modes, the capillaries are co-ordinately affected. If this influence is depressed as well as otherwise altered, locally or generally, either by the operation of the cause, or by pre-existing disorder, a state of action characterised by deficient power is the result. The specific forms which inflammation assumes when arising from certain causes, particularly from infection or inoculation, depends upon the mode or nature of the morbid impression made upon the organic nervous tissue of the part, especially that distributed upon, or interwoven with, the capillaries. The causes may act by their continued presence; thus irritating bodies, or the lesions of structure produced by chemical agents or by injury, may prove sources of irritation to the nerves and capillaries of a part; but more frequently the exciting causes change, by the impression made at first by them, the degree, mode, or state of influence exerted by the organic nervous tissue upon the capillaries and smaller vessels, and upon the fluid circulating in them; the resulting morbid action presenting corresponding and peculiar characters in respect of kind, degree, and power or tone. This is more remarkable in the more specific forms of inflammation, either produced by certain poisonous agents, or attending some constitutional maladies.

155. In experiments upon living tissues, the effects produced by various stimulants and astringents have in some respects been misinterpreted by the experimenters; and the slight constriction of the capillaries that directly follows the application of such substances, and before the dilatation which subsequently occurs, has been viewed as the first part of the inflammatory act. But this effect depends upon the action of these substances, particularly of turpentine, alcohol, the salts, and many others, upon the vital contractility of the tissues and extreme vessels. The instant effect of these is more or less constriction of the capillaries; but this very soon ceases, the natural state, or expansion beyond it, soon following. When the substance employed is of an irritating nature, without any astringent property, an enlargement of the capillaries is the next phenomenon to follow the impression made by it upon the organic nervous tissues; this impression being frequently rendered instantly and acutely sensible. In observations or experiments made upon the living tissues, care should be taken to distinguish between the effects produced, — 1st, upon the organic sensibility; — 2d, upon the organic contractility; — and, 3d, upon the physical properties of the tissues — upon their cohesion, elasticity, &c., or upon the properties which animal substances continue to manifest some time after death. The *first* of these ceases instantly with dissolution; — the *second* remains for a short time afterwards, but is soon exhausted by strong stimuli; — and the *third* continue much longer, but gradually disappear with the supervention of decomposition, yet admit of being more or less preserved and somewhat modified by various substances of an astringent and antiseptic nature. In the investigation of the nature of the changes in living structures, usually called inflammatory, the intimate relation existing between these changes, and the causes which induced them, should not be overlooked. The mode of operation of the causes, especially with reference to the vital and physical properties just enumerated, and to the local and general circulation, ought to be strictly regarded; and the manner in which the results may be modified by constitutional predisposition should be taken into account.

156. *d. The state of circulation in the early stages of sthenic inflammations.* — The primary affection of the organic nervous tissue having been shown to be one of *morbid excitement in the sthenic forms of inflammation*, and the effects of this excitement to be *turgescence, enlargement, or active expansion of the capillaries*, it next remains to inquire as to *the state of the circulation in the enlarged vessels*. This topic has been much discussed, for observations of the current of blood in the capillaries are liable to error; and besides, the flow of blood may be retarded at a single point, and greatly accelerated at others, particularly when inflammation is produced by mechanical or chemical agents. The state of circulation also undergoes a succession of changes, as will be hereafter shown, with the progress of the disease. It will not be denied that the organic or ganglial nervous tissue exerts a manifest influence, not only upon the capillary circulation, but also upon the blood itself; and that the secreting and other organic functions are under the dominion of this part of the nervous system. It consequently follows, that excitement, depression, or other affections of this influence, will produce co-ordinate changes, not only in the capillaries and related vessels of a part, but also in the state of circulation and in the blood in them. During excitement of the organic nervous functions of an organ, the vessels experience not only an expansion, but also an increase of tone — a vital turgescence. The capillaries, although increased in diameter, still retain the power of reacting insensibly upon the blood propelled into them, so as to preserve, if not to accelerate, the rapidity of the currents passing through them. The necessary result of these states is an increased flow of blood, and a rise of temperature, and these effects continue until the excitement is exhausted, — varying, however, in feature as well as in continuance, and more especially in the associated phenomena and consequences, with the mode or kind of excitement directly resulting from its cause.

157. When the propelling power of the heart and the tonicity of the larger arteries give rise to an increased *vis à tergo*, and particularly when the expansion of the extreme vessels is such as to allow a portion of their contents to escape through the delicate or imperfect canals in which they terminate, or when an obstacle is opposed to the return of the blood through the veins, a portion of the red particles escapes with the serum into the inflamed tissue, generally at minute or distinct points. This is observed especially when the tone of the capillaries in an inflamed part is exhausted, either by the nature of the exciting cause, or by

the previous excessive excitement, before the increased action of the heart has subsided.

158. *e. Of the development of new vessels in inflamed parts.* — It is not only the vital turgescence or expansion of the capillaries, so that those which could not admit the coloured globules of the blood in the healthy state readily admit them in an inflamed part, but also the developement of new vessels that is often observed. But this latter event takes place chiefly in serous membranes, and especially in albuminous exudations from the inflamed surface. It possibly may also occur in other parts, to a more limited extent, although it does not admit of so obvious a demonstration as in these. It can only occur in the various grades of sthenic inflammation, and it fully evinces that, although truly morbid in its nature, this form of the disease is characterised by vital activity, and by a deranged increase of the formative process in the affected part. In asthenic inflammations, however much capillary canals may be enlarged so as to admit a greater column of blood, no new vessels are developed, unless the asthenic be converted into the sthenic state. In the former state of disease, the expansion is the result of impaired vital tone and resistance, both of the capillaries and of the tissues affected; and the organic nervous power of the part, and the action of the capillaries upon their contents, are incapable of forming either coagulable lymph or new vessels. In the latter state, nervous power and vascular action are capable of producing the one, and often also the other.

159. When sthenic inflammation affects serous membranes, the morbid exudation thereby formed on their surfaces is sufficiently consistent to admit of the extension or growth of new vessels from those which had become enlarged in the early stages of the inflammatory act, and to give them support until they acquire considerable development. But when the asthenic disease implicates these membranes, the secretion from their surfaces is too watery or serous to furnish consistent canals or channels in which the contents of the capillaries may be conveyed beyond those which are morbidly enlarged, without commingling with the rest of the effused matter. In cases where new vessels form, the exuded lymph or albumen, into which they run, is not only to a certain extent consistent, but also somewhat scanty, or at least not very abundant; but in cases where they cannot be formed, the fluid effused is generally both serous and copious.

160. The production of new vessels in parts sthenically inflamed, particularly in exudations of lymph, is observed chiefly in young persons, and especially in these who are in the course of development. Occasionally the new vessels are numerous and distinct, even before the lymph had become at all abundant or consistent. In some very beautiful injected preparations by Mr. KIERNAN, the eminent pathologist, that he kindly showed me, this was most remarkably demonstrated; as well as the fact, which has been controverted by some French pathologists, that the new vessels shoot out from the inflamed surface, if not from those enlarged in the early stage of the inflammatory act. When new vessels form in the fibrinous lymph exuded from serous membranes, they may often be injected,—the continuity of these vessels with those of the affected part being thereby clearly shown. Yet the most vascular part of the newly organised false membrane may not be that nearest the seat of inflammation,—the new vessels forming several anastomoses, and occasionally becoming enlarged in some places at a distance from the surface whence they were produced.

161. *f. Consecutive changes in the sthenic forms.* — The successive changes taking place in the course of sthenic inflammations are conformable with the laws of the animal economy. The excitement produced in the organic nervous tissue and capillaries of the part is exhausted with a rapidity, and to an extent, in proportion to its intensity relatively to the powers of the constitution, and of the part affected; and as the exhaustion proceeds, the tonicity of the extreme vessels and of the diseased tissue, as well as the vital cohesion of both, is weakened, the circulation through them retarded, and the colour of the blood deepened. The extent to which these changes take place, in connection with the degree of general vascular action, and of constitutional power, fully accounts for the lesions consequent upon sthenic inflammations. When phlegmasia arises from specific causes, the kind of morbid excitement primarily induced by them will, according to their nature, more or less modify these changes, and give rise to certain results in preference to others. We perceive this in the exanthemata and in various inflammatory diseases. The tissue affected will also modify the continuance and mode, as well as the consequences, of the morbid excitement. But there can be no doubt that the successive alterations in the inflamed structures are merely consequences of the morbid impressions made by the exciting causes upon the organic nervous tissue, particularly in its connection with the capillaries; the states of these and the connected vessels, of the circulation through them, of the blood, and of the diseased part, being the effects which may either disappear before the vital resistance of the frame, or terminate in any of the ways described above (§ 39, *et seq.*).

162. *B. Of the Nature of the Asthenic States.* — The remarks which I have just offered more especially refer to the *nature of the more sthenic inflammations*, and it is, therefore, necessary to consider *the circumstances in which the asthenic states differ from these.* It has been shown that these states proceed chiefly from constitutional predisposition, or from previous or associated disorder, or from the nature of the exciting cause. In either case, the organic nervous influence, and, consequently, the tone or vital contractility of the tissues and capillaries in the seat of the disease, are quickly exhausted or readily depressed, and soon become otherwise morbidly affected,—effusion, softening, disorganisation, or gangrene, taking place with a rapidity in proportion to the primary vital depression, or to consequent exhaustion, and to the nature of the impression made by the exciting cause. In cases of asthenic inflammation, either there has been originally, or acquired, great debility or deficiency of the organic nervous power, or the assimilating and excreting functions have been long disordered and imperfectly performed, or the exciting cause has been of a powerfully depressing or poisonous nature. Indeed, two, or even all, of these circumstances may be concerned, each more or less, in the production of some one or other of the morbid states of action comprised under the

more generic appellation, asthenic inflammation. Owing to one or more of these circumstances, the vital contractility of the capillaries and tissues of the affected part is impaired; vital cohesion is weakened, so as to occasion remarkable softening and friability of the structures; the tone of the extreme vessels is so far lessened as to admit the effusion, and percolation through the more yielding tissues, of the more serous portions of their contents, sometimes coloured by red particles; the vital resistance of the capillaries, owing to the loss of tone, is insufficient either to resist even the weakened impetus of the blood, or to react upon it so as to carry on the circulation through them and the venous capillaries; and, ultimately, increased effusion, retardation or stagnation of the blood in the minute vessels, and all the consequences shown to result from the asthenic forms of inflammation (§ 70, *et seq.*), take place. Throughout the course of asthenic inflammations, the states of organic nervous influence, of vital action in the extreme vessels, and of the circulation in the affected part, are incompatible with the production of coagulable lymph; and hence the effused fluid infiltrates the more soft surrounding tissues, and, owing to its morbid condition, caused by the states of vital action and of the blood, contaminates them, or promotes their disorganisation.

163. The *distension* of the capillaries in asthenic inflammations is referable to impaired or lost tone, rather than to an active vital expansion or turgescence similar to that which characterises the early stages of sthenic inflammations; or, if the latter state exist at first, as it probably does for a very short time, in the less asthenic cases, it soon exhausts itself, and passes into atonic distension, with retarded circulation. But there is every reason to infer, that the current of the blood is impeded or retarded in the capillaries at an early stage, or even from the commencement, of many cases of asthenic inflammation, particularly those caused by septic agents or animal poisons; and that the blood soon becomes stagnant in them, the various consequences, already noticed, appearing according to the intensity and rapidity of the previous changes upon which this has been shown to depend. In proportion, generally, as the circulation is retarded in the extreme vessels, the temperature of the inflamed part sinks, and the colour becomes deep or livid, until a purplish or brown hue is acquired. As soon as these changes take place, disorganisation soon follows, and proceeds with a rapidity in proportion to the weakness of vital power and resistance. If the organic nervous energy be aroused or reinforced by appropriate constitutional and local means, the mischief may be arrested, unless it have already proceeded beyond the powers of restoration, and it may be ultimately remedied, as in the advanced stages of sthenic inflammations. When the asthenic forms are arrested at an advanced stage, they generally assume more or less of the characters of the sthenic condition, reparation taking place as in that form of the disease.

164. *C. Of the Intermediate States of Vascular Action and Vital Power in Inflamed Parts.*— As shown in the article DISEASE (§ 87, *et seq.*), the states of organic nervous influence and vascular action do not always present specific grades or forms, which certain terms can precisely represent. The terms applied to morbid action are entirely relative; and whilst we use the appellations *sthenic* and *asthenic*, to convey an idea of the more extreme and opposite states of nervous power, and of vascular action, we must not overlook that every intermediate form and grade may exist between them. To describe states, so diversified as these are, is obviously impossible. All that can be attempted is to notice certain circumstances generally appertaining to them. — The organic nervous power, evinced by certain inflammations, may not materially vary in *kind* from the natural standard or condition, and yet vascular action may be excessive and very acute, or much more moderate, and, consequently, more protracted, or slight, and more or less chronic. The forms of inflammation, particularly as respects the acute, chronic, and intermediate or sub-acute states, result chiefly from the grades of organic nervous excitement and vascular action; whilst the more specific characters which they present depend principally upon the conditions of the organic nervous energy, as regards not only the *amount* of the excitement or depression, but especially the alterations or *deflections in kind* from the natural habitudes of this energy. Whilst the *activity* of the inflammation depends chiefly upon the grade of vascular action in the inflamed part, in connection with the degree of general vascular commotion, the *specific character* of inflammation arises principally from the truly diseased impression made upon the organic nervous tissue of the part, and from the change thereby effected in the influence of this tissue on the vascular system, such change being in the kind, rather than in the degree, of organic nervous influence.

165. The varieties of ERYSIPELAS, the local inflammations attending the different *exanthemata*, and, indeed, the numerous specific forms of inflammatory action induced by these and other infections or animal poisons, are illustrations of alterations in the *kind* or *mode*, rather than in the *degree*, of local and general organic nervous energy and vascular action. In these, and in all the asthenic states of inflammation, there is a much more remarkable alteration in kind from the natural standard than in the sthenic forms. The *intermediate states* between the most fully expressed sthenic and asthenic conditions depend chiefly upon specific or other deviations in kind — *upon the truly morbid changes* now contended for, especially such as immediately proceed from the nature of the exciting causes, or from contagion. The principal of these, owing to their specific form, are fully discussed under appropriate heads.

166. *D. Of the Existence of different States of Capillary Tone and Circulation in the same Inflamed Part and the Vicinity.* — Much of the discussion which has taken place as to the capillary circulation in inflamed parts has been owing to the variations in this state during the course of the disease, and to the different vital conditions of the capillaries and of the small arteries, in different parts, or in the several tissues comprised in the seat of inflammation. — When compound or parenchymatous structures are inflamed, such differences or variations are the most remarkable, particularly if the disease has commenced at a single point. At this point, especially, the tone of the capillaries becomes the soonest exhausted, and the current of the blood retarded; and these states increase the vital turgescence of the surrounding

vessels, and accelerate the circulation through them. When the substance of an organ is inflamed, the fibrinous lymph exuded at the point first affected, often retards, by its pressure, the circulation in the vessels at this point; and owing to this obstruction, the surrounding vessels are the more readily developed, and more prone to become morbidly turgescent. The lymph effused also affects the vitality of the part, either occasioning more or less irritation to the organic nervous tissue, or perpetuating or modifying the disorder of this tissue already existing, that caused its effusion. Müller thinks that the lymph coagulates in the extreme capillaries, when the inflammation is seated in the substance of an organ; but I believe that it is exuded in the areolæ of the structure, thereby rendering the part more solid or dense; the change thus produced having been termed condensation, solidification, hepatisation, or splenification, according to the appearances assumed, and to the organ affected. It is only in the sthenic forms of inflammation that the effused fluid gives rise to these changes, as shown above.

167. If the intensity of the morbid action in the spot first affected be so great as to exhaust its organic nervous power or its vitality, and to retard its circulation, or to stagnate the blood in the capillaries, not only do the surrounding vessels become more turgescent and developed, but the blood which has thus stagnated, and the tissue itself, undergo very material changes, as described above (§ 156.). Hence very opposite states of the circulation generally exist in different parts of the seat of inflammation, especially when the disease is advanced. In cases of injury, particularly of laceration, pressure, or other changes, the capillary circulation is often directly obstructed; and either independently of lesion of the organic nervous tissue and sensibility, or aided by such lesion, diseased vascular turgescence is thereby developed around the seat of injury, — the capillaries thus obstructed, and the blood contained in them, soon undergoing changes productive of suppuration, or ulceration, or gangrene, whilst sthenic vascular action is either proceeding in the surrounding turgescent vessels; or passing into exhaustion or into the asthenic condition, progressively from the point of injury, or from the spot first affected, according as the constitutional powers may resist, or may favour, the extension of the mischief.

168. *E. Of the State of the Venous Circulation in Inflamed Parts.* — There is every reason to believe that the venous circulation is locally more than usually active in the sthenic and acute forms of inflammation; but that it is more or less languid in the asthenic varieties. When the former, also, goes on to suppuration, and especially to ulceration, the circulation in the veins, more immediately proceeding from the part, is generally somewhat retarded, the retardation increasing these changes. Hence the importance of favouring the return of blood from the part by position, when these consequences of inflammation have taken place. Whenever the venous circulation is obstructed, effusion and œdema increase rapidly in the part affected, and in its vicinity; and the consequent retardation or stagnation of the blood in the capillaries, induces or accelerates disorganisation. This is observed very frequently in erysipelas, and constantly when the inflammatory action extends to the veins — which not infrequently occurs when the constitutional powers are depressed, or in the more asthenic forms of the disease. In such cases the local lesions are remarkably increased, not only by the stasis of blood in the capillaries, but also by the more copious morbid effusion caused by the obstructed return of blood.

169. *F. Of the Function of Absorption in the Seat of Inflammation.* — In the early stages of sthenic inflammation especially, absorption seems to be less than usually active; but, when the disease proceeds to ulceration, or even to suppuration, and when it assumes asthenic forms, then the absorbent action is often increased, although there are numerous exceptions to this, absorption sometimes being manifestly impaired. When the absorbents become inflamed, owing to the morbid nature of the cause, or of the matter formed in the primary seat of disease, then more or less of obstruction results, and the function is arrested, great tumefaction of the parts beyond the obstruction taking place, and increasing the local mischief by pressure and by the contaminating influence of the morbid secretion. In obstructed venous circulation the swelling increases rapidly, chiefly from augmented effusion; in impeded absorption it advances with nearly equal rapidity, from the fluid being undiminished by removal. In either case the effused fluid undergoes material changes during its retention, and becomes more and more hurtful to the tissues containing it, and more irritating to the vessels which may absorb it.

170. It was supposed by John Hunter and others, that *ulceration* depends upon increased activity of the absorbents of the part, when inflammation has reached a certain period of its progress. But I believe that it is chiefly owing to the superficial softening or loss of the vital cohesion at that part of the inflamed tissue where the extreme vessels have lost their functions, and to the solution of the molecules of the tissues in the fluid effused from the diseased surface (§ 48.). Absorption is probably also concerned in the process, and in various degrees, according to the seat of the inflammation, and the states of organic nervous or constitutional power and of vascular action.

171. *G. Of the States of the Blood in the Capillaries of Inflamed Parts.* — The blood circulating in inflamed parts presents very different appearances with the form and stage of the disease. In the sthenic forms, and particularly in the early stages, before any of the more unfavourable consequences have supervened, the blood is florid, and partakes much of the characters of arterial blood; but in the asthenic forms, and less remarkably in the advanced stages of the sthenic, it is more venous, or of a darker hue. It is sometimes quite purplish, or blackish, particularly when a tendency to sphacelation or gangrene occurs. Also, as it circulates in the capillaries, the globules seem, under the microscope, gradually to move more slowly, and to be attracted by the sides of the vessel, or to stagnate in the capillary canals. This change seems to commence in the smaller or capillary veins, and to extend, especially in the asthenic states of inflammation, in the direction of the minute arteries, the temperature sinking with the deepening of the hue, and with the loss of motion of the blood globules. In other respects the

blood presents the appearances already described with reference to the different forms of inflammation. (See § 25. 66.)

172. iii. Of Reparation of the Consequences of Inflammation. — Reparation of the effects of inflammation is accomplished only under the influence of life, although much assisted by art. It may be very briefly considered, with reference, 1st, to the removal of those changes more immediately resulting from inflammation that are independent of loss of substance; and, 2d, to the restoration of disorganised or of lost parts, where either has taken place. Whether morbid depositions are to be removed, or losses of substance are to be supplied, restoration of the manifestations of life in the various organs to their healthy states is the chief intention to be fulfilled. Frequently nothing more than the subsidence of the morbid action in the affected part is necessary to the reparation of the injury done; but often something more is requisite, and the aids of science are needed to assist in the work of restoration.

173. *a.* The *softening*, or impaired vital cohesion of the inflamed part, the *fluids effused* in the areolæ of the tissue, and the coagulated lymph thrown out upon a serous surface, or poured into the porous structure of an organ, so as to solidify it, will generally be removed, when the morbid action which caused these changes has altogether subsided. With the return of the functions of the part, the vital cohesion will be restored, and the activity of absorption will gradually remove the fluids effused in the substance, or upon the surface, of an organ. If the lymph have become partially organised, or have formed false membranes on serous tissues, or have agglutinated the opposing surfaces of shut cavities, the difficulty of removal will be increased, and the time of effecting it prolonged. But if the inflammatory action be entirely subdued, the object will be ultimately attained, and with a rapidity and certainty in proportion to the restoration of the powers of life throughout the frame. Even when the coagulated albumen is organised into false membranes, or into cellular adhesions, their extent and their vascularity will gradually diminish, and they will either entirely and slowly disappear, or become merely lax bands, or thin films, offering little or no impediment to the functions of the parts which they connect. Yet, where such adhesions form, a disposition to returning inflammation will generally exist, or the morbid action which produced them will continue in a much slighter and chronic state. It is chiefly to these circumstances that most of the unfavourable results consequent upon adhesions are owing. The lymph effused in the areolæ of a parenchymatous viscus, as in hepatisation or splenification of the lungs in pneumonia, is commonly soon removed with the subsidence of the disease, and much more rapidly and certainly than the lymph poured out upon a serous surface. The albuminous exudations sometimes formed on mucous membranes very rarely or never become organised, but are detached and thrown off as the diseased action subsides, by an increased secretion of mucus from the follicles underneath. In the course, however, of their excretion from the canals which those membranes cover, they often occasion remarkable disturbance, severe spasms, or even death by asphyxia, especially when they form on the respiratory surfaces, as in *croup*, *laryngitis*, &c.

174. *b.* When the organic nervous and vital powers continue but little impaired, serous and albuminous fluids effused during inflammation are generally removed upon the subsidence of diseased action, although the rapidity and completeness of removal will depend much upon the nature, consistence, and extent of the effusion, and the states of constitutional energy. If the fluid is truly purulent, and especially if it form an encysted or circumscribed *abscess*, restoration is then generally difficult, and only to be accomplished, particularly when the collection is deep-seated, either by absorption, or by the extension of the abscess to an external or internal surface, as is fully shown in the art. Abscess (§ 30.). When the fluid of an abscess is absorbed, nothing but a firm cicatrix, generally linear, or irregular and circumscribed, is observed in its former seat. But when it finds its way to a surface, and is evacuated, either the patient sinks under the local lesion and discharge, and the constitutional disturbance, or the work of reparation proceeds under the influence of the vital energies. In this latter case, the discharge from the surface of the abscess becomes albuminous, the parietes contract, and the cavity diminishes. Instead of pus, an albumino-puriform fluid is secreted, which gradually becomes more and more albuminous and scanty. The fluid exuded upon the internal surface of the abscess at last passes into the state of coagulable lymph, under the restoring influence of the organic nervous energy; it becomes vascular, and healthy granulations thus form, and fill up the cavity which the contraction of its parietes is incapable of obliterating; and thus the injury and loss of substance are repaired.

175. In the reparation of *ulcerated* parts a similar process takes place. The softening and solution of the molecules of the tissues in the fluid discharged from the ulcerated part are first arrested by restoring organic nervous energy, by local or constitutional means, or by both. Thereby a more healthy secretion takes place, and suppuration is established, and is followed by granulation in the manner just described, the mischief being thus repaired. Ulceration is most prone to occur, and to proceed rapidly, in parts exposed directly or indirectly to the air, or to the contact of irritating matters; and in those which are most distant from the centre of the circulation, and in which the capillary circulation is naturally weak or slow. Hence it is of importance to the reparation of an ulcerated part, to protect it from those sources of irritation. When an ulcerated surface is extensive, and the tone of its vessels much impaired, the discharge is generally so copious as to detach from it all applications calculated to protect it from irritation, and is so injurious or contaminating as to increase the mischief, if allowed to remain any time in contact with it. The first object in such cases is to restore the organic nervous energy, and tonicity of the capillaries of the part, and thereby to diminish the quantity, and to improve the quality, of the discharge. The fluid subsequently exuded on the diseased surface will often of itself serve as a protection; and applications which restore the tone of the extreme vessels, and diminish or coagulate the discharge, whilst they further protect

the part, will then be of service, complete reparation taking place under the eschars or scabs, sometimes thus formed. In this manner, strong solutions of the nitrate of silver, or other stimulating and astringent substances, often act very beneficially on ulcerated surfaces, whether the discharge coagulate on them or not. But this subject will be more appropriately considered hereafter.

176. *c.* In cases of *divided* or *injured parts*, when the blood, or the fibrinous lymph exuded from the capillaries, coagulates so as to protect them entirely from the air, and without allowing coagula or any other substance to remain that may occasion irritation, the healing process often proceeds without any evidence of phlegmasia taking place. When divided parts are brought in contact, after the hæmorrhage from them has ceased, the lymph exuded from the opposing surfaces will first slightly agglutinate, and afterwards perfectly connect them, small capillary vessels penetrating and organising the connecting medium, which will diminish more and more as it becomes firmly organised. In this process, which has been called by surgeons, "*union by the first intention,*" inflammatory action can hardly be said to exist. If it actually take place, very different phenomena present themselves. This process has, however, been described as a consequence of phlegmasia, — probably owing to the circumstance of inflammation actually taking place in some parts or other of the surfaces, the union of which is thus attempted, and which various causes prevent from uniting, and chiefly by exciting inflammation in them. It is very rare that divided surfaces entirely unite without this disease being excited in some portion or other; for incongruous parts or tissues are often brought together, that are incapable of uniting directly. These must necessarily become inflamed, and give rise to the usual consequences of phlegmasia. Moreover the fluids and blood effused from the divided structures, and the ligatures placed upon the larger vessels, are sources of irritation, seldom failing of producing inflammatory action, although the more congruous tissues may have perfectly united. In all such cases, union has taken place in the uninflamed parts only. (See the *Local Treatment of* Inflammation.)

177. VIII. Treatment. —The treatment of inflammation must necessarily be guided by a variety of circumstances and considerations. The chief of these refer, — 1st, to the disease itself; 2d, to the individual affected; and, 3d, to the nature of the exciting causes. — *a.* The character, form, progress, and consequences of the inflammation, existing at the time of treatment, should be carefully weighed, as these severally require very different, or even opposite, indications and means. — *b.* The age, strength, temperament, diathesis, habit of body, modes of living and occupations of the patient, ought also to be taken into consideration, and the treatment modified accordingly. — *c.* The exciting causes, the states of constitutional predisposition, and the predominating influences to which the patient is subjected, should be ascertained as fully as possible, and the means of cure selected with strict reference to them. — As the form and character of the inflammation depend chiefly upon the circumstances here alluded to, I shall discuss the treatment which observation has shown me to be most appropriate and successful in each of the principal forms under which I have described this important class of diseases.

178. i. Treatment of Sthenic Inflammations.— *A. Acute Phlegmasia.* — *a. At an early stage* of all sthenic inflammations, the *indications of cure* are — 1st, to lower general and local vascular action; 2d, to equalise the circulation, and to derive from the seat of disease. Several of the means which are employed to fulfil the *first*, also often accomplish the *second* indication.

179. (*a*) *In order to lower general and local action*, numerous agents are usually prescribed according to the peculiarities of the case. These operate either upon the system in general, and indirectly upon the part affected, or immediately upon the latter, and consecutively upon the former, according to their natures, and the manner of employing them. — *a.* Of those which act in the first of these modes, *bloodletting* is one of the most important. It has been, however, very much abused; and the cure of inflammations has too generally been attempted by it chiefly, or even alone. There are numerous circumstances which either very remarkably limit, or entirely contra-indicate, the employment of bloodletting, in those morbid conditions in general, which have been all denominated inflammation, although differing greatly from each other; and even in this, the least equivocal form of the disease, there are many considerations which should weigh with the practitioner in limiting the amount of the depletion on the one hand, or in inducing him to carry it far on the other. The extent to which it may be prescribed should be determined by the age, strength, temperament, diathesis, and habit of body of the patient;— by the constitutional symptoms; — by the vital importance and structure of the part affected; — by the duration of the inflammation; — by the states of the pulse and of the blood first drawn; — by the effects produced by a former depletion; — and by the condition of the tongue, skin, and urine.

180. If the patient be young and robust, and well nourished — if the disease be very acute, or seated in a vital organ, or serous surface — and if the constitutional affection be of a manifestly sthenic kind, — the quantity of blood taken at first should be very considerable, and it ought to be taken in such a manner as to make a decided impression upon the circulating system as soon as possible — or in a large and full stream, so that the rapidity of the abstraction may assist the quantity in the effects produced upon the disease. As I have recommended in the article Blood (§ 64.), the depletion should be effected whilst the patient is in a semi-erect or semi-recumbent posture, in order that the desired approach to syncope may be more certainly produced, without, however, causing syncope, for the reasons fully explained in the article just referred to. — The first abstraction of blood ought to be instantly followed by the means about to be noticed (§ 196.); but the circumstances now stated as demanding a full or large depletion in the first instance, will require a repetition of it, generally to a less amount, but in strict reference to the local and constitutional symptoms, to the effects produced, to the time which has elapsed from the first

bloodletting, and to the appearance of the blood then taken away.

181. The *pulse*, the *blood*, and the character of the *pain* in inflammations, furnish many useful indications as to the *institution*, the *repetition*, and the *amount* of *depletion;* but they may mislead most remarkably, if the numerous exceptions they afford, and the circumstances in which these exceptions occur, be not taken into account. — In inflammations of vital organs, and particularly of the stomach, of the intestines, or of the substance of the brain or liver, the very intensity of the disease may produce so severe an effect upon the constitution, — so violent a shock to the vital powers, — as to deprive the *pulse* of firmness or tone, and to cause not only an oppressed, but also a weak, small, slow, or an irregular, state of pulse. In such cases the practitioner must not be deterred from bloodletting by this circumstance; for after a few ounces of blood are abstracted, the pulse will become more full, strong, and regular. In all inflammations, especially of vital parts, depletions should be performed with a most attentive regard to the phenomena whilst the blood is flowing; and in cases similar to those alluded to, the effects ought to be most assiduously watched. If the pulse rise in strength, and especially if it become hard, as well as developed or full, the bloodletting may even at first be carried so far, as to make an impression upon the circulation, and to reduce the pulse again in strength and fulness. — When the pulse is open and throbbing, or jerking, as generally observed after copious hæmorrhages, bloodletting will rarely be of benefit, although it has not been already resorted to, and it may be most injurious. Where a moderate bloodletting produces sinking or syncope, without affording relief, it will be injurious to pursue the practice further, if, indeed, it has not already been prejudicial.

182. A hard, tense, or strong pulse, not only requires a very copious depletion at first, but generally also a repetition of it. If a pulse, which was too frequent and too full, is reduced in these respects — or if a hard, constricted, or small pulse is softer and freer — or if a pulse hitherto slow and oppressed has become more natural, — it may be concluded that the bleeding has been of service, and that it may be safely repeated to a less amount, if the symptoms require it. If, on the contrary, the pulse has become weak, hurried, compressible, open, jerking, irregular, or intermittent, without producing relief, the bleeding has already proved injurious, and a repetition of it would be productive of danger. It may be taken as a general rule, that when the pulse is above 110 and compressible, whatever may be the organ inflamed, the system will not bear general bloodletting even in the first instance. The local abstraction of blood, however, with caution, may prove of service.

183. The *appearances of the blood* first abstracted have generally influenced the physician more or less in prescribing a repetition of depletion. But they ought to be considered in strict connection with the other symptoms. The appearances most deserving of notice are — the firmness or looseness of the crassamentum; the proportion it bears to the quantity of the serum; and the presence or absence of buffiness, and cupping of its surface. In the article Blood (§ 96, 97.), and in a previous section (§ 25.), I have fully discussed the appearances of the blood indicative of sthenic inflammations. These should receive attention in practice; but I may here remark, that although a cupped and buffed state of the crassamentum is evidence of an excited state of the circulation, and very frequently attends inflammation, yet alone, or without the presence of other symptoms indicating the propriety of bloodletting, it is no proof that this measure has been indicated, or that its repetition is requisite. When, however, the crassamentum is large, firm, or dense, and the buffy coat is considerable, thick, firm, and tenacious, the other signs of inflammation being present, depletion may be repeated, and occasionally oftener than once. If the clot be loose, has a thin or an irregular edge, and especially if it be small relatively to the quantity of the serum, a repetition of depletion will be injurious. In all cases the appearance of the blood depends much upon the manner in which it is taken, — especially upon the size of the orifice, the posture of the patient whilst the blood flows, and the shape and size of the vessel in which it is received. A buffy, cupped, and firm coagulum will form in a deep or narrow vessel, particularly if the blood flow rapidly; whilst neither of these appearances will occur if it be received in a wide and shallow vessel.

184. The *pain* and other local symptoms ought also to guide the practitioner as to the extent to which depletion should be carried. But these should not be exclusively confided in, for the most violent pains, as shown above (§ 82.), are generally independent of inflammation, and are not abated by vascular depletions. Nor are all alterations of sensibility depending upon inflammations to be relieved by bloodletting; for the most severe pains accompanying asthenic inflammations will very often not be even mitigated by it, although altered sensibility in the sthenic forms, now more especially under consideration, will generally be entirely removed by it, if it be actively and judiciously practiced. As long as pain and tenderness on pressure continue, the pulse being firm, resistant, or constricted, and not very frequent, general bloodletting may be repeated, although some exceptions to this rule may present themselves; but in most of these, local depletions may be employed. If the pain return after having disappeared, or if it become exasperated, although bloodletting has been instituted, a repetition of the measure is necessary, unless the other symptoms obviously forbid it; for, in this latter case especially, the first depletion has only relieved the load which overwhelmed the sensibility of the organ, and a second, or even a third, is requisite to restore the circulation of the part to its healthy state.

185. The *absence of pain* ought to be no argument against resorting to vascular depletion, if other symptoms indicate the propriety of it; for intense inflammation may exist in the parenchyma of an organ, particularly the brain, the liver, the lungs, or the kidneys, and even in mucous or serous membranes, without pain being complained of, or without sensibility being further disturbed than is indicated by a feeling of heat, or of oppression, or of weight.

186. The *functions* of the inflamed organ ought also to indicate the propriety of repeating deple-

tion. When they are restored, then the chief object is attained, and no further loss of blood should be inflicted on the patient; but if they continue to be suspended or disordered, or if they are only partially restored or improved, local depletions, at least, are required, especially if due time have been allowed for the first bleeding to produce its effects.

187. The *tongue* furnishes important indications as to the propriety of general or local bloodletting. When the papillæ are distinct and erect, the tongue being white or loaded, and inclined to be dry, or its edges or point, more or less red, vascular depletions are generally necessary. When the fur on the tongue is erect and white, and the sides and point red, blood may be taken away, if no symptoms contra-indicate the practice. On the other hand, when the papillæ or the fur is flat, and the tongue very moist or watery on its superior surface; when it is broad, flabby, fissured, or lobulated; when its edges are indented by, or retain the impression of, the teeth; when it is pale, especially at its point or edges; when it is tremulous on being held out; and when it is covered by a thick, dark mucus or fur; bleeding is generally inadmissible.

188. When the *cutaneous surface* is hot and dry throughout, depletion will be of service; but if it be cold, clammy, and shrunk, or if it be covered by a hot clammy perspiration, bloodletting will be inappropriate, as the chief objects intended to be accomplished by bleeding are to lower general action and to produce relaxation, and these are already attained. If the *urine* is high-coloured, scanty, and does not deposit a sediment, bloodletting may be practised, if other symptoms do not contra-indicate it; but if the urine be pale, limpid, and copious, it will generally be injurious.

189. Besides these guides to the institution and repetition of vascular depletion, there are various others, appertaining to the organ affected, &c., which should guide the physician; but these do not come under consideration at this place. The age, constitution, and diathesis of the patient, and the other states of predisposition, as well as the exciting causes, however, require some notice. The very young (infants) and the aged should be depleted with caution. Persons of a nervous or lymphatic temperament cannot bear so large losses of blood as those who are sanguine, irritable, or sanguineo-melancholic. In the gouty and scrofulous, in the previously diseased, in the ill-nourished, in the very obese, and in persons of a relaxed fibre, or leucophlegmatic or cachectic habit of body, such losses are generally injurious.

190. The nature of the *exciting causes*, and the *influences, mental and physical*, operating on the patient during treatment, should greatly influence the amount of vascular depletion. Inflammations consequent upon active excitement, or attending vital reaction, are most benefited by this measure; whilst those caused by septic, poisonous, infectious, or contaminating agents, are generally aggravated by it. All the depressing affections of mind, an air loaded with malaria or paludal exhalations, the foul air of hospitals, and the confined atmosphere of large towns, particularly in crowded dwellings, in low cellars, in close lanes or alleys, and in manufactories, frequently not only prevent the good effects of bleeding from ensuing, but also render its institution or repetition injurious.

191. The *prevailing epidemic constitution*, or the general character presented by epidemic and other diseases, should always be kept in recollection, especially as respects the employment of bloodletting. The inflammations which occur in the puerperal states, erysipelas, and the inflammatory complications observed in the courses of exanthematous and continued fevers, vary remarkably in their particular characters, according to the prevailing constitution. At the period of change from one general constitution to another, it is very difficult at once to determine upon the admissibility of bloodletting, particularly as regards the diseases just named, and others allied to them; but close observation of the morbid phenomena, and attention to the circumstances and considerations now enumerated, will lead to a right determination as to this practice. Generally speaking, also, it will be found, that all inflammatory diseases attended by a free state of the secretions; by copious fluid defluxions, particularly from the seat of disease; by a moist or relaxed skin, or irregularity and weakness of pulse; by physical and mental depression, and especially by great despondency, unfavourable anticipations of the result, or indifference to objects of former or natural endearment; will either not be relieved, or will be aggravated, by bloodletting.

192. *β. Local depletions* are often sufficient in many forms, states, or stages of inflammation, to accomplish the ends in view. The circumstances requiring *local*, in preference to *general bloodletting*, are chiefly the following: — 1st, The slighter states of inflammatory action; — 2d, Forms of the disease approaching to, or partaking of, the asthenic condition; — 3d, A stage of inflammation too far advanced to admit of, or to be benefited by, general depletion; — 4th, When venesection has been carried so far as not to admit of its repetition, the disease being either unsubdued or only mitigated, and requiring to be aided by this means; — 5th, When it is desirable to derive from the seat of disease, as well as to deplete moderately; — 6th, When it is wished to remove local congestion of the vessels, and to restore the sensibilities and functions of the affected part; — and, 7th, When inflammations occur in debilitated, nervous, or delicate constitutions, and as complications of febrile, or other diseases.

193. The *modes* in which local depletion should be performed also require attention. When a considerable quantity of blood is to be abstracted, and it is desirable to effect a rapid derivation from the seat of disease, then *cupping* is to be preferred; but when the quantity is to be small, and when the application of warm fomentations and poultices to the part subsequently is likely to be serviceable, then *leeches* are more appropriate. Where the morbid sensibility and situation of the parts prevent the having recourse to cupping, a large local depletion being requisite, then a great number of leeches should be applied. In such cases the fomentations and poultices used to promote the bleeding will act beneficially in soothing the altered sensibility, upon which much of the diseased action depends. When the part inflamed admits of the direct application of leeches, it is often doubtful whether they should be placed upon it or not; for in some constitutions the punctures of

leeches are followed by much local and general irritation, or even by erysipelatous inflammation; and if a small number be employed, they only increase the local irritation and determination, without unloading the vessels of the diseased part. In these cases, depletion by more or less numerous or deep scarifications is sometimes more beneficial than by leeches, especially if the vessels are much engorged. It should also be recollected that bleeding by leeches occasions much greater depression, relatively to the quantity of blood abstracted, than by any other mode, especially in nervous and susceptible persons; and that in some constitutions and situations the bleeding from their bites is not readily arrested. When the vital tone and cohesion of the tissues are much weakened, as in febrile and malignant diseases, a fatal loss of blood may take place from them, if the bites be not watched for a considerable time after they are removed. In some cases, *cupping over the bites* of leeches is very advantageous, in abstracting both a greater and more determinate quantity of blood, in preventing a prolonged and weakening discharge from them, and in determining the circulation to the part to which they were applied.

194. In visceral or internal inflammation it has often been recommended to apply leeches over the seat of disease; but, unless some advantage be expected from the subsequent fomentation, no additional benefit will result from the selection of this situation; and, if an intimate vascular connection exist between the part inflamed and that to which leeches are applied, the blood may be injuriously determined thereby to the former place.—When the phlegmasia is entirely visceral, the application of leeches to that part of the external surface which is over the seat of disease, probably effects as complete a derivation from it as when applied to any other situation; whilst the subsequent fomentation tends to equalise the general circulation, and to determine to the surface of the body.

195. In conclusion, the propriety or impropriety of repeating bloodletting in inflammation, as well as of adopting it in the first instance, cannot be inferred from one symptom or consideration alone. The constitution, habit of body, and previous state of the patient, the condition of the various functions, the increase or decrease of the pain and other morbid phenomena in the affected part, and the other circumstances stated above, should chiefly influence our decision upon these important points of medical practice.

196. *γ. Calomel and opium*, as so ably recommended by Dr. Hamilton, should be prescribed in a full dose immediately after the first bloodletting, whenever the inflammation presents an active or sthenic form. In acute phlegmasia of a vital or important organ, from ten to twenty grains of calomel, and from two to three of opium, and one grain of ipecacuanha, may be given at once. This combination will generally succeed in keeping down the general morbid action to that grade to which it had been brought by the depletion, and in preventing reaction from following thereupon. It will also relax the cutaneous surface, determine to the skin, and thereby equalise the circulation. In some cases, smaller doses, especially of the calomel, may be given, and repeated every fourth, fifth, sixth, or eighth hour, according to the urgency of the case, until a decided effect is produced upon the disease. In all sthenic inflammations, the specific effect of mercury upon the tongue and gums is not readily produced; but as soon as it begins to appear, the mercurial medicine should be relinquished, or the dose of it reduced. It is chiefly in cachectic persons, and in the asthenic forms of inflammation, particularly when vascular action is languid or low, or when there is but little excitement, that mercurials, especially in large quantities, are injurious. When sthenic phlegmasia is seated in serous membranes, or extends to them, the decided use of mercury in the combination just prescribed, or in others hereafter to be noticed, is most requisite, in order not only to aid in the resolution of the morbid action, but also to prevent effusion, or the exudation of coagulable lymph, and the several ill consequences shown to depend upon effusion in its various states.

197. When inflammation implicates serous, fibrous, or even parenchymatous parts, preparations of *antimony*, especially James's powder or tartar emetic, may be combined with the calomel and opium, particularly for phlegmasia of the serous membranes of the chest and of the brain, and for pneumonia, &c.; but when mucous surfaces are inflamed, especially the intestinal mucous surface, *ipecacuanha* is preferable, and it may be given in large doses, as two, three, or four, or six grains, in the form of pill, with a full dose of opium. In many cases, also, *camphor* will be beneficially conjoined with calomel and opium; but when it is to follow a large depletion, or when sthenic inflammatory action is not fully subdued, it should be prescribed in small doses, so as to act as a refrigerating diaphoretic. It is chiefly in asthenic inflammations that full or large doses of camphor are required.

198. The *repetition* of calomel and opium, with or without either of the other medicines just mentioned, as to frequency, or the intervals between the doses, as well as the quantities of both, should entirely depend upon the intensity, the seat, and the other circumstances of the disease. The largest doses already mentioned should not be frequently repeated, unless in the most urgent cases. In some instances it may even be sufficient to give them only after each depletion, or to prescribe also, in the intervals, smaller quantities, as may be required. In the less severe states of inflammation it will be preferable to prescribe much smaller doses, as from two to five or six grains of calomel, and a quarter or half a grain of opium, every four, six, eight, or twelve hours, according to the peculiarities of the case, in combination with either of the other medicines already noticed. After depletion has been decidedly employed, these doses will generally be sufficient, even in the more severe cases, and will often give complete relief, without affecting the mouth, their good effects being manifested chiefly on the general and local states of action, on the skin, and on other excreting organs.

199. *δ. Purgatives.*—Unless it be desired to produce a very speedy effect upon the system by calomel or other mercurials given in the above combination, an occasional or even frequent recourse to purgative enemata will generally be necessary, although purgatives taken by the mouth may not then be requisite. Purgatives, however, are amongst the most important remedies used in the treatment of inflammations; their good effects depending upon several circum-

stances:—1. They evacuate morbid secretions and fæcal accumulations, which injure the organic functions, and depress or otherwise derange the powers of life, and which thereby favour the extension of the local affection, and increase the constitutional disturbance; — 2. They diminish vascular fulness, by increasing the intestinal exhalations, and the secretions of collatitious organs, and thereby lower febrile action;—3. They determine the blood to the digestive mucous surface, and derive it from remote parts. Owing to this last circumstance, they should be given with due caution when the digestive tube, or even when the viscera associated with it, are inflamed. They are more serviceable in some inflammations than in others; thus they are more efficacious in congestions and inflammations of the head, than in similar affections of the abdominal and thoracic viscera. The selection of, and modes of administering, purgatives, also, are matters of great importance; but are so intimately dependent upon the nature of individual cases, that no general rules can be stated as to these topics. The refrigerant purgatives are usually the most appropriate, as the sulphate of magnesia, and other neutral salts, either alone or with the infusion of senna; the bitartrate of potash with jalap; the spirits of turpentine with castor oil; calomel with the compound extract of colocynth, or with jalap, &c. One of the best modes of administering these medicines is to give them at first, or a few hours after a full dose of calomel or blue pill, in briskly cathartic doses, so as to clear out the bowels, and afterwards to keep up a more gentle action by milder and cooling doses, or by suitable enemata, or by both. The operation, as well as the antiphlogistic effects of these, and of other purgatives that may be employed, will be promoted by adding to them the potassio-tartrate of antimony, or ipecacuanha.

200. ε. *Mercurials.*—Although calomel is one of the best purgatives that can be given in this class of diseases, yet it, as well as other preparations of mercury, is often required for its alterative effects chiefly, not only after bloodletting has been practised, and as above advised (§ 196-8.), but also where depletion should not be adopted. In some cases it is necessary to use every means, and even several simultaneously, in order to arrest the usual course of the disease, particularly in inflammations of serous membranes, and of the larynx, trachea, iris, &c.; and one of these means is the rapid production of the specific effects of mercury. These effects being produced, not only is the resolution of the local morbid action thereby favoured, but also effusion is diminished, and the disposition to form coagulable lymph is entirely prevented. Hence mercurials employed with the view of affecting the system are most useful for inflammations of parts which give rise to albuminous exudations; and are either of little service, or even prejudicial, when prescribed for inflammations of cellular or parenchymatous structures, especially if these assume a diffusive, or spreading, or irritative form. In such cases, other means, hereafter to be noticed, will be found more beneficial. But in acute sthenic inflammations, neither mercury nor any other means should interfere with bloodletting. It may assist in subduing, and in removing, several of the effects of these diseases, but it should never wholly supersede vascular depletion in some form or other. In chronic inflammations, however, where alterations of structure have commenced, and where they are but little influenced by depletion, mercury is one of the most efficient means that can be prescribed for the prevention of further effusion, or other change, and for promoting the absorption of whatever deposition may have already taken place.

201. ζ. *Spirit of turpentine* is hardly known as an antiphlogistic remedy; and yet, from an experience during nearly thirty years of its effects, both in sthenic and asthenic inflammations, I believe that none is more deserving of confidence, if appropriately and prudently prescribed. As I have long ago shown (*Lond. Med. and Phys. Journ.* for July and August, 1820.), the operation of this medicine depends upon the dose, the frequency of the repetition, and the combinations of it with other remedies. Hence it may be made available in every form of inflammation. In the sthenic form it is remarkably serviceable after depletions have been duly practised, and it may be used both internally and externally — in draughts, or in enemata — in liniments, embrocations, or fomentations. In all inflammations tending to copious effusion, or to fibrinous exudation, after bloodletting has been resorted to, and more especially when it becomes doubtful whether general depletion should be prescribed, or repeated, or not, this substance, in hands experienced in its operation, is a most valuable remedy. In these cases it should be given in quantity sufficient to act upon the bowels and kidneys,—either one drachm twice or thrice daily, or from three to six drachms once a day, alone or with castor oil. It may also be administered once or twice a day in enemata in larger quantities. Where it is desired to produce as rapid an impression as possible upon the malady, not only should the one mode of exhibition be made subsidiary to the other, but both should be aided by the external use of this substance, in the form of a warm embrocation, fomentation, or epithem. In such cases I have generally directed several folds of flannel, large in proportion to the extent and severity of the disease, to be wrung as dry as possible out of very hot water, to be instantly freely sprinkled with spirit of turpentine, and applied immediately over the affected organ; to be closely covered, when thus applied, by wash leather, or a dry cloth, to prevent evaporation; to be kept thus applied as long as possible, or as the patient may endure it; and to be renewed as circumstances may require. In less severe cases, or at the commencement of inflammation, I have found a single application of this fomentation instantly arrest the disease, without depletion or any other means beyond a purgative medicine having been employed. In chronic inflammations, the *liniments* containing this substance, prescribed in the Appendix (F. 296. 311.), may be used either as such, or as embrocations, or they may be applied over the affected organ, on the surface of warm flannel, in the way just described.

202. The spirit of turpentine, thus employed internally or externally, or both, need not prevent a recourse to calomel, or other mercurials, but may be used, particularly in the more urgent cases, in conjunction with them,—the former aiding the operation of the latter. Although one of the most efficacious means of arresting inflammation and its consequences, there is no remedy that requires more discrimination and experience of its action

and effects, than this. Much of the disappointment sometimes felt as to its operation has been entirely owing to the inappropriate use of it, and to injudicious modes of prescribing it. The practitioner who is well acquainted with its effects, in the various doses and modes of using it, will find it most effective in lowering general action when inordinately excited; in controlling local disease; in arresting the effusion of morbid fluids consequent thereon; and in determining the momentum of the circulation to the intestinal canal, to the urinary organs, or to the cutaneous surface, according as either effect may be desired; and thereby in deriving from the seat of disease.

203. η. *Refrigerants and diaphoretics.*—Of these, the former are generally used in aid of more active measures, with the view of reducing the increased temperature, which aggravates or perpetuates the local morbid action; and the latter are prescribed with the intention of restoring or increasing the cutaneous functions, of thereby equalising the circulation, and of removing a portion of the serous and excrementitious elements in the blood. In many cases, substances acting both as refrigerants and as diaphoretics are most appropriate, or those which exert the former action more readily produce the latter effect. Indeed, whenever vascular action is sthenically excited, the skin being hot and dry, it is necessary to lower the general action, and to give such substances as act in this manner, as the most certain means of procuring perspiration. In the majority of cases, after vascular depletion and other evacuations have been duly employed, the cooling diaphoretics are thus indicated; and, although more active means may be still requisite, particularly those already described, yet these will generally be found useful when taken in the intervals, or as occasions may offer. The diaphoretics which will be found most beneficial are the solution of the acetate of ammonia, camphor, spirit of nitric æther, and a solution, or the wine, of the potassio-tartrate of antimony, which may be variously combined according to the peculiarities of the case.

204. *Warm, vapour,* and *medicated baths* are amongst the most energetic diaphoretics; but much judgment is required in prescribing them; for their effects will entirely depend upon the form, state, seat, and stage of the inflammation against which they may be employed. In acute sthenic inflammations, they should not be resorted to until vascular depletion has been duly employed, and alvine evacuations freely procured. When, however, the stomach or bowels are inflamed, they may precede the use of means for the evacuation of the latter. In chronic inflammations of the internal viscera, or of the joints, fibrous tissues, &c., vapour baths, various fumigating baths, and particularly those with sulphur or camphor, warm baths, especially those containing the decoctions of emollient herbs, or weak alkaline solutions; aqueous vapour with the fumes of camphor, or this latter conveyed around the patient; may severally be brought most advantageously in aid of other appropriate means.

205. ϑ. *Diuretics* are sometimes required in the treatment of inflammations, not merely on account of any derivation from the seat of disease thereby procured, but with the view of reducing whatever serous plethora may exist; and of removing from the circulation, by increasing the action of the kidneys, those ultimate products of assimilation which are liable to accumulate in the blood to an injurious amount, during the febrile state, and thereby to heighten the local affection. With this intention, several of the more refrigerant diuretics may be advantageously employed, especially the spirits of nitric æther, the bitartrate of potash, and the neutral salts in small doses. They may be taken either in the patient's usual drink, or conjoined with the other medicines required by the particular circumstances of the case.

206. ι. *Narcotics* are occasionally beneficial, especially when inflammation is attended by great pain and irritability, and in the sthenic forms after vascular depletion and alvine evacuations have been duly practised. *Opium* and the *salts of morphia* are the narcotics most frequently prescribed, although *hyoscyamus*, *belladonna*, &c. may likewise be employed in some circumstances.—Opium was much recommended for inflammation by medical writers during the seventeenth and eighteenth centuries, and frequently in combination with other medicines; but its use, or rather its abuse, was also greatly condemned. There are few medicines which require greater discrimination than this, and particularly when given in this class of diseases; for the propriety of having recourse to it will entirely depend upon the seat, stage, and form of the inflammation, upon the constitutional symptoms, upon the means previously employed, and upon the dose and combination in which it is prescribed. Dr. ARMSTRONG advised large doses of opium after bloodletting, in a paper published in 1824 in the "*Transactions of the Associated Apothecaries*," under the belief that the advantages derived from the combination of calomel and opium, recommended by Dr. HAMILTON, were entirely to be ascribed to the latter substance alone. In this, however, he was altogether mistaken; for this single remedy is not nearly so beneficial as in combination with calomel and the other medicines mentioned above (§ 196-8.). Nor, indeed, did the practice present any originality; for it had been employed by numerous writers and practitioners long before he advocated it, even before the periods which I have already assigned. Besides other instances in which I had prescribed it with great benefit previously to this time, I attended a case of phrenitis in 1820, with Mr. CARROLL of Walworth, in which three grains of opium were given at one dose, after bloodletting had been carried sufficiently far. In slighter cases, after vascular depletion and the operation of a cathartic, a large dose of laudanum, or of solid opium, has manifestly aided greatly in tranquillising the nervous system, in reducing vascular action, and in procuring refreshing sleep; the patient awaking with a soft or moist skin, and with freedom from pain. Dr. STOKES has recently adduced evidence in favour of this practice, and shown that it is peculiarly beneficial in cases of recent inflammation of serous and mucous membranes, where bloodletting and other antiphlogistic remedies are inadmissible, and where the system is greatly depressed. In most instances, however, opium, or the salts of morphia, will be more advantageously combined with calomel, as above advised (§ 196-8.), or with ipecacuanha, or with camphor, or with James's powder, or the other preparations of antimony. Where pain is so excessive as to constitute the most prominent symptom, it is a most important remedy. When great exhaustion follows bloodletting, owing to its having been carried too far, or improperly resorted to, opium and camphor con-

joined are most valuable medicines; and in the asthenic forms of inflammation especially should never be overlooked, particularly in conjunction with other means. The salts of morphia in similar combinations will be found equally beneficial.

207. The other narcotics, as *hyoscyamus, conium, stramonium, belladonna*, &c., are less useful in inflammations, and not so generally appropriate as opium; and yet instances often occur, in which a large dose of some one of these, according to the features of the case, may be preferred; and, after bloodletting and alvine evacuations have been duly practised, and in the combinations already mentioned (§ 196-8.), will be found frequently of service. The chief recommendations in favour of these are—the circumstances of their not interrupting or suppressing the functions of secretion and excretion, and of their relaxing spasm of circular fibres and canals, as well as allaying irritation. It should, however, be admitted, that when opium is prescribed in large doses, it does not interrupt secretion or constipate the bowels so remarkably as when given in smaller quantities; and that these effects are then frequently even not observed.

208. *κ. Sedatives.* — Of these, *colchicum* is the most active; and in certain kinds of inflammation especially, as the rheumatic and gouty, the most serviceable, when prudently prescribed. In the sthenic forms, also, of phlegmasia, it may often be advantageously brought in aid of other means. When it is desired to promote the secreting functions of the kidneys, and thereby to eliminate from the blood urea and its combinations, or other materials which would increase the local and general affection, if allowed to accumulate in the blood, then colchicum may be made a valuable remedy. Also, when inflammations are attended by a torpid or obstructed state of the liver, this medicine, conjoined with deobstruent purgatives, will be of essential service. In cases attended by very acute pain, or by the effusion of fluids from the inflamed part, it will also be of service, particularly when judiciously combined with other means; but its action should be carefully watched, as in some constitutions it produces most depressing and even injurious effects. It is best conjoined with camphor, the alkaline carbonates, magnesia, the neutral salts, and other purgatives; and is most serviceable after depletion and alvine evacuations.

209. *Digitalis* has been more generally employed than colchicum in inflammatory complaints, although it is a less efficient, and even a more uncertain, remedy than it. As long as vascular action is acute or sthenic, digitalis, even in large doses, exerts but little influence upon the circulation; whilst its cumulative effects will sometimes appear as soon as the symptomatic fever abates. It is most serviceable as an adjunct to other means, whose operation is more decided and certain, especially where effusion has commenced, or is about to commence, from the diseased part; when inflammation attacks debilitated, cachectic, or delicate persons, who cannot bear general or free bloodletting; and when it assumes slight, chronic, or subacute forms.

210. *The preparations of antimony*, particularly the *potassio-tartrate*, given in large and frequent doses, produce a sedative, or, according to RASORI and his followers, a *contra-stimulant*, effect. After causing vomiting, they act upon the bowels and skin, and reduce the pulse in strength, fulness, and sometimes in frequency. For inflammations of the thoracic viscera, and of the brain and its membranes, a decided and judicious use of these medicines, after due vascular depletion, is generally of great service; but they should never supersede this latter, although they may prevent the having recourse to very large or repeated bloodlettings. In other circumstances, as well as in those just instanced, these preparations are very beneficial, particularly when conjoined with opiates or other narcotics; they lower general and local vascular action, relax the cutaneous surface, favour perspiration, and equalise the circulation.

211. The potassio-tartrate of antimony is seldom prescribed as an emetic in sthenic inflammations, unless in those affecting the respiratory organs and passages. In order to procure its depressing effects, a quarter or a third of a grain is usually given every two or three hours. The first two or three doses may cause vomiting, but nausea and a lax state of the skin and bowels will subsequently be the chief effects. Chronic inflammations are often subdued by this medicine, and the most successful results frequently follow it in delicate constitutions, when bloodletting does not promise any decided advantage. It should not, however, be carelessly employed, as I have seen it productive of the most injurious effects when pushed far in debilitated persons, and in young children. In smaller doses, as from the one fifth to the one tenth of a grain at the same intervals, it produces a salutary diaphoresis. To effect this, however, it is seldom given alone, but is usually conjoined with camphor mixture, solution of the acetate of ammonia, the spirits of nitric æther, and sometimes with a small quantity of sulphate of magnesia or of the nitrate of potash.

212. The employment of large doses of tartar emetic in inflammations originated in Italy; and although it was at first discouraged by British practitioners, yet the experience of the ablest physicians in this country and on the Continent has now fully decided in favour of the practice. Since 1819, I have generally resorted to it in the manner just mentioned, especially in the treatment of inflammations of the respiratory organs, and generally with great benefit. There are few cases which, if promptly treated by bleeding, and subsequently by this medicine, will not be very materially relieved; and in those which have been neglected, or in which the proper time of bleeding has gone by, this substance, with mercury, or with the solution of the acetate of ammonia, or with opium if it irritate the digestive canal, or with other appropriate means, will frequently prove of great service.

213. The empirical powder, introduced by Dr. JAMES, is the next to tartar emetic, as an efficacious preparation of antimony in the treatment of inflammations. The *pulvis antimonii compositus* in the *Pharmacopœia*, which was intended as a substitute for it, cannot be depended upon. The different effects of these medicines have been attributed by Dr. THOMSON to the fact of the antimony in the former being a protoxide, which is soluble; in the latter a peroxide, which is insoluble. Mr. PHILLIPS seems to confirm this in his translation of the *Pharmacopœia*. In numerous cases of inflammation, and in many circumstances, *James's powder* should be preferred to any other antimonial. In *children*, particularly those which are very young, and for inflammations of

the pulmonary organs, as well as of the brain and its membranes, in this class of patients, it is generally the best preparation of antimony, and the best sedative, that can be prescribed.

214. *Cold* is one of the most powerful sedatives, and one which is not always judiciously employed. There are few agents which are more efficient in constricting the vessels of the part, than it. Also, by altogether removing the principal stimulus to, as well as the chief consequence of, vascular excitement, namely, increased temperature, it prevents the consequent exhaustion of the tone and vital cohesion of the capillaries and inflamed tissues. Yet, in medical practice, its appropriate use is comparatively limited; for it cannot be brought to act upon the majority of internal inflammations in such a manner as to insure its good effects, or without interfering with other means upon which still greater dependence may be placed. It is also applicable only to the sthenic and acute forms of inflammation; for it is generally injurious in the asthenic and specific varieties, particularly the diffusive, erysipelatous, gouty, and rheumatic. In all cases of visceral inflammation where the application of cold tends to constrict the external surface, and to determine the circulation to internal parts, cold can rarely be advantageously prescribed; for even when employed internally, or in enemata, it can seldom be prevented from superinducing reaction, or be so applied as to keep down vascular action for a continued or prolonged period. It is, however, different with inflammations of the brain or of its membranes; for the comparatively superficial and isolated situation of the diseased parts, their distance from the centre of the circulation, the minute division of the vessels in these organs, and the complete manner in which cold applications may be made to surround the whole seat of disease, — in the form of the cold affusion, the ice-cap, evaporating lotions, &c., — combine to render cold more beneficial in these inflammations, than in any others affecting internal organs.

215. It has likewise been recommended to employ cold in the treatment of other visceral inflammations, as in pneumonia, enteritis, peritonitis, &c. Breathing very cold air has been tried in the first of these by practitioners of the United States of America, and cold applied to the abdomen in the others by Dr. SUTTON and by several German physicians, but with very doubtful advantages. Indeed, the results of such practice may be tolerably accurately inferred *à priori*.

216. Amongst other sedatives, mention may be made of the *tepid bath*, and the *tepid affusion* or *douche*. These, by abstracting heat, exert a depressing effect, and slightly constrict the surface. When the heat of skin is very considerable, the pulse being rapid and somewhat hard or resistant, the tepid bath is to be preferred to the warm bath, as it not only cools the surface, but also generally favours diaphoresis with more certainty than this latter. Indeed, in acute sthenic inflammations, the warm bath should not be used of a higher temperature than 96°, unless in cases presenting peculiar features. The tepid bath, or affusion, is frequently more appropriate in the early and acute stages of inflammation than the cold on the one hand, or warm, vapour, or medicated baths, on the other; as it gradually reduces the temperature without favouring the occurrence of reaction. Warm, vapour, and medicated baths are most serviceable at advanced periods of inflammation, after evacuations have been freely procured, or when the disease becomes chronic or complicated.

217. *The abstraction of all causes of irritation*, as well as of the exciting causes of the disease, is obviously requisite in the treatment of inflammation. The excitement of the senses, especially of the organs of sight and hearing, and of the mental faculties, should be carefully guarded against. Muscular action, and stimulation of the stomach by heating food and beverages, ought also to be prevented; the antiphlogistic regimen being strictly enforced in all its parts.

218. λ. *Derivatives and counter-irritants.*—These should never be employed until the general vascular excitement is subdued by bloodletting and other evacuations; and until a powerful impression has been made upon the local affection. These ends being attained, the *mode* of derivation or counter-irritation should next be considered. This should depend upon the seat, form, and duration of the inflammation, and the consequences to which it may already have given rise.—In acute cases, and at early stages of the disease, the *hot turpentine epithem*, or application, already described (§ 201.), is the most efficacious, the safest, and the most immediate in its effects. It should always be applied over the inflamed organ, or as near it as possible. It is applicable to all forms of inflammation, in whatever organ they may be seated. It tends, more than any other derivative, to determine the circulation to the cutaneous surface, and to prevent the more dangerous consequences of the disease.

219. *Sinapisms* are extremely serviceable, and produce their effects rapidly, but they are less efficacious than the turpentine epithem. — The application of the strong *solution of ammonia*, with tincture of camphor and spirit of rosemary, as advised by Dr. GRANVILLE, is also of use, and especially in weak, irritable, or nervous persons, and when inflammatory irritation is attended by much pain. It produces a very rapid effect, and either a superficial and slight, or a more severe and caustic, action, according to the duration of the application. — The liniment employed as a counter-irritant by the notorious empiric, St. John Long, was recently analysed by Dr. MACREIGHT, who found it to consist of oil of turpentine and acetic acid, held in suspension by yolk of egg. Having prepared a liniment consisting of *one ounce and a half of oil of turpentine, of one ounce of strong acetic acid, three ounces of water, and the yolk of one egg*, the three last being rubbed together, and the first being afterwards added, Dr. MACREIGHT found it, in its sensible properties and effects, to be identical with the empirical medicine. That a liniment consisting of these ingredients should prove of essential service in many cases, cannot be doubted. For upwards of twenty years, and for several years before this fashionable empiric appeared, I had frequent recourse to a liniment, consisting of equal parts of the compound camphor liniment and the compound turpentine liniment, with a little cajuput oil, as a counter-irritant; varying it, however, according to the peculiarities of the case, and as prescribed in various parts of this work, and in the APPENDIX (see F. 296. 311.). When this liniment, or any of the others just referred to, is applied on the surface of

warm flannel, or of a cloth wrung out of hot water, over the situation of internal or deep-seated inflammations, it produces an almost immediate effect. But friction during ten or fifteen minutes with the cold liniment will give rise to erubescence, sometimes to exudation, and more or less decided relief. In acute cases, the former mode of application may be adopted; but in chronic or sub-acute inflammation, particularly when alteration of structure has taken place, repeated frictions with this liniment, short of inflaming the skin, are often to be preferred. When the irritation produced by it gives rise to vesication or abrasion of the cuticle, the parts soon heal; but it is frequently of service to continue this effect for some time, by the repeated or prolonged use of the application.

220. *Blisters* may be employed as counter-irritants in three modes: — 1st, as rubefacients; — 2d, as simple and slight irritants; — and, 3d, to procure a puriform secretion from the part. In acute inflammations they ought not to be prescribed until bloodletting has been carried as far as circumstances will permit; and in early periods of the disease, they should not be applied longer than seven or eight hours, and a warm bread and water poultice should be placed over the part, to promote the vesication, and to prevent the irritation sometimes consequent on them. It will occasionally be advisable to place tissue paper between the blister and the surface. On *children*, blisters ought not to be applied longer than from three to six hours, and warm poultices should generally replace them, and be renewed frequently. For sub-acute and chronic inflammations, or for the advanced stages of the acute, blisters may be prescribed for a longer period, and sometimes with the intention of procuring a sero-puriform discharge from the blistered surface.

221. *Warm pediluvia*, the *hip-bath*, and the *semicupium*, are often useful modes of derivation, when the head or the thoracic viscera are affected, or when it is desirable to excite the uterine discharge. Their effect will generally be promoted by the addition of mustard and of common salt to the water. But, in acute inflammations, the temperature should not be too high, or such as may heighten the general vascular action. They also ought not to be resorted to until depletion and alvine evacuations have been duly practised. Besides these, there are other substances sometimes used to produce counter-irritation and derivation, as *croton oil*, the powder or tincture of *capsicum*, bruised *garlic*, and scraped *horseradish*. They quickly produce a rubefacient action when applied on the skin; but are not so efficient in the severer cases of acute inflammation, as those previously noticed. They are all, however, often of service, particularly in the slighter forms of the disease, that are attended by acute pain. Besides these, *cupping* with scarification, and *dry-cupping*, are serviceable modes of derivation in the sthenic forms of phlegmasia.

222. The foregoing modes of counter-irritation are most serviceable in recent, acute, or sub-acute inflammations. Those which are about to be noticed, act chiefly as suppurants, and are most suited to the chronic states, or to the more advanced stages, or rather to certain of the consequences, of the acute and sub-acute forms of inflammation. They consist chiefly of ointments or plasters containing the *potassio-tartrate of antimony*, or *cantharides*, or *savine*; the decorticated *bark* of the *mezereon root*, moistened in water or vinegar, and applied to a small portion of the cutaneous surface; *croton oil*, either alone, or suspended in twice the quantity of camphor or soap liniment or olive oil; *issues* and *setons* of various forms and kinds; *moxas*, and the *actual* and potential *cauteries*. The exact circumstances requiring either of these means in preference to others are so numerous, — the choice of them depending so entirely upon the seat, peculiarities, and stages of the disease, upon the constitution and diathesis of the patient, and upon the other remedies employed, — that no general rules can be stated for the guidance of the inexperienced in this respect; the powers of observation, experience, and views of the practitioner must be his chief guide in the adoption of these, as well as of many other means of cure.

223. It has been very justly remarked by my early friend and former colleague, Dr. Dunglison, in his very judicious observations upon the use of revellents in the phlegmasiæ (see his excellent work, entitled, *General Therapeutics, or Principles of Medical Practice, &c.* 8vo. Philadelph. 1836, p. 363.), that when we are desirous of maintaining a succession of revulsions, or a constant revulsion, we employ either repeated blisters, or keep the blistered surface discharging by applying some of the other means just mentioned. Tartarised antimonial ointment is well adapted for chronic inflammations, as of the lungs, — because, whilst the pustules induced in any one part of the exterior of the thorax, or elsewhere, are going through the stages of increment and maturation, a fresh crop may be elicited on some other part of the chest; and thus a succession of irritations can be developed, which is more beneficial than one that is more permanent.

224. It is of importance to determine the *extent of surface* to be affected by a revulsive application. This is not always so easy a matter as may be supposed; for, if the vital conditions be affected by it in a very limited extent of surface, the morbid action, intended to be remedied, may be entirely uninfluenced by it: and, on the other hand, if a very large surface be irritated, constitutional disturbance will be thereby excited; or that depending upon the primary disorder, as well as the disorder itself, will be aggravated or perpetuated. — As to the *time*, during which the counter-irritation should be maintained, but little can be stated; for it must depend almost entirely upon the circumstances of the case. On this topic, Dr. Dunglison remarks, that it is chiefly when the diseased action has been prolonged for a considerable period, and in affections of a neuralgic kind, that sudden and violent revulsions are productive of the most marked advantage. In the different phlegmasiæ, revulsions which implicate a greater extent of surface, and are more prolonged in their action, are decidedly preferable. In the former cases, moxas and the cauteries may be employed; in the latter, rubefacients and vesicants.

225. The permanence or remittence of the counter-irritation deserves consideration in every case for which this means is prescribed. In most of the phlegmasiæ, remittent revulsion is more serviceable than a prolonged or permanent revulsion. Dr. Dunglison justly observes, that when an artificial irritation, accompanied or unaccompanied with increased secretion from the part, has been

established for some time, it ceases, in a great measure, to be a morbid condition, and cannot be arrested without an inconvenience, or risk to some organ predisposed to disease; but if a succession of irritations be produced, the system never becomes habituated to them, and the repetition of the irritation, after a short period, is as beneficial as at first. A succession of vesicants, therefore, is to be preferred to a more permanent application; setons and issues losing much of their beneficial influence in the latter periods of their employment.

226. BROUSSAIS, and many of his followers, have contended that revulsive irritations should be stronger than the morbid action they are intended to replace, otherwise they tend to increase the latter; but although it is manifestly necessary to reduce the inflammation as much as possible by depletions, before counter-irritants are prescribed, yet great good will result from the judicious use of them. There are also several that may be very safely employed early in some of the phlegmasiæ, and even before depletions have been practised, as the turpentine epithem, liniments, &c. (§ 201. 219.). I therefore agree with Dr. DUNGLISON, in believing that good will be derived from revulsants in appropriate cases, even should they fall short of the precise degree necessary for completely putting an end to the disease for which they were prescribed.

227. The *situation* to which revulsants or counter-irritants should be applied, relatively to the seat of inflammation, is deserving of attention, especially as a contrariety of opinion exists on the subject. And yet the very terms here used ought to guide the practitioner to the application of them to parts which are not supplied with branches of the same nerves and blood-vessels as proceed to the seat of disease. Much, however, should depend upon the nature of the adopted revulsant; for the turpentine epithem or embrocation will never be injurious, but generally beneficial, however close it may be applied to the inflamed organ. But it is different with blisters and other counter-irritants. I cannot agree with Dr. THOMSON's and Dr. CHAPMAN's recommendation to place these "as near as possible to the affected part." I have often seen mischief result from the early application of a blister to the scalp in meningitis and encephalitis, and to the throat in laryngitis and tracheitis. When, however, the inflammation is of an asthenic or adynamic kind, or when the sthenic form has given rise to effusion, blisters, as well as several other counter-irritants, may generally be applied close to the diseased organ. Yet, even in these circumstances, exceptions to the rule are not few. The choice of situation must therefore depend upon the seat and character of the phlegmasia, and other peculiarities of the case: precise directions respecting it can be given only when discussing the treatment of particular inflammations. In all cases the choice should be guided, as M. BEGIN remarks, by sound physiological principles; for they only can render this mode of practice more certain than it has hitherto been, and prevent the inconveniences which often follow it.

228. It has been already stated that blood-letting, both general and local, may be so instituted in several of the phlegmasiæ, as to derive from the seat of disease. The older writers paid much attention to this method of depleting. Bleeding from the saphena vein, the feet and legs being immersed in warm water, was often prescribed for phlegmasiæ of the viscera, and particularly when consequent upon suppressed evacuations: and bleeding from the vicinity of the anus by leeches is generally adopted by foreign physicians, for inflammations of the liver, stomach, &c. Indeed, to derive the impetus of the circulation from the seat of the phlegmasia by vascular depletion, by cathartics or other evacuations, and by counter-irritants or other revellents, both internal and external, must always be a principal indication of cure, in this class of diseases.

229. *μ. Of applications to the inflamed part itself*, there are some that require a particular notice. They may be all comprised and considered under the following modes of operation: — 1st, Those which reduce the temperature, and thereby remove one cause of morbid irritation, and of vascular expansion; — 2d, Those which soothe the morbid sensibility or diminish pain, either by their influence upon the affected nerves, or by diminishing the tension, rigidity, or pressure of parts; — 3d, Those which constringe the expanded capillaries, restore their lost tone, and prevent the stagnation of the blood or promote the circulation in them; — and 4th, Those which protect the part from external irritants, &c. It is obvious that many local applications produce benefit by acting in more than one of these modes; but still they may be referred to one or other of these especially. Moreover, many internal means of cure act upon the part affected, particularly in visceral phlegmasia, in one or other of these ways. As *topical means* are applicable chiefly to external inflammations, which are generally viewed as belonging to the province of the surgeon, my remarks respecting them will be as brief as the importance of the subject will permit. Yet it must not be overlooked, that most external inflammations, particularly when spontaneous, are merely symptomatic of constitutional disorder — are only the external manifestations of visceral or general disturbance, or of hereditary vice, — that they all react upon the frame through the medium of the organic nervous and vascular systems, — and consequently, that, whilst local remedies form only a part of the treatment required, the rest being employed with reference to the internal and constitutional affections, the entire treatment, even in the external phlegmasiæ, is more strictly medical than surgical, if, indeed, the distinction should be at all entertained.

230. (*a*) *Of those applications which directly reduce the temperature*, some notice has already been taken (§ 214.). They have generally the effect, not only of removing a principal cause of excitement and irritation, but also of constricting the morbidly expanded vessels. *Cold applications* are, however, often injurious, and consequently inappropriate or hazardous, whenever the external inflammation is merely the outward expression of internal or constitutional disorder, as in gout and erysipelas: they are less so, however, in sthenic than in asthenic or specific inflammations. For in the sthenic phlegmasiæ, the vital energies are capable of resisting their sedative influence, and the suppression of the local affection rarely endangers internal viscera. But in the other kinds of inflammation the repulsion of the external affection often caused by these applications is frequently followed by serious internal disease. In such cases the source of mischief is in the frame,

and in some important or vital organ; and when the effects are prevented from appearing externally, they often break out in some internal viscus.

231. Of the numerous *cold applications*, there are few which are preferable to the *solution of the di-acetate of lead*, inasmuch as it combines astringent with cooling and sedative properties. But this, as well as the common *cooling* or *evaporating lotions*, and *cold or tepid water-dressings*, should be suited to the intensity of the inflammations, and be used unremittingly, until the local affection is subdued; for if employed only at intervals, or if at all intermitted, reaction will take place in the inflamed part, and the disease will be thereby aggravated, or at least perpetuated. We observe this in the treatment of *scalds* by cold applications, when used in this latter mode. When the inflammation is of a specific or asthenic kind, and when it is attended by great tumefaction and excessive pain, or when cold applications do not give relief to the pain in a short time, they ought either not to be employed at all, or not to be continued, but give place to very different means. Also when they produce general chilliness, they ought not to be persisted in.

232. (*b*) *Applications which soothe the morbid sensibility* are perhaps more generally appropriate, and are certainly less dangerous in the symptomatic or specific phlegmasiæ just alluded to, than those which are cold. They all more or less diminish the tension of rigid and unyielding tissues, lessen pressure on sensitive parts, and have an emollient and soothing effect. *Moist warmth*, employed in various ways, but especially in the form of *steam, simple and medicated*, and of *fomentations, poultices*, and *warm baths*, also either simple or medicated, &c., is the principal agent by which the physician or surgeon produces these effects. *Steam*, or warm aqueous vapour, has lately come into notice in the treatment of inflammations; and we are indebted to Dr. MACARTNEY and Dr. WILSON for a knowledge of its virtues in respect of its topical external use; for as regards its internal employment by *inhalation* in affections of the respiratory organs, it has been long prescribed. (See ASTHMA, and BRONCHI — *Inflammations of*.) In the form of the vapour bath, it has also been generally used, particularly in circumstances already noticed (§ 204.). By very simple yet suitable appliances, *steam*, either of water alone, or of water containing various *narcotic* or *emollient herbs* or *extracts*, or *camphor*, or *acetous* or *terebinthinate substances*, may be brought in contact with, or entirely surround, the seat of inflammation. It may likewise be *inhaled* into the lungs for the affections referred to, either in its simple or medicated states. When employed externally, and particularly to a limited extent of surface, it should be continued for a very considerable time, and at a somewhat higher temperature than when inhaled. The substances, also, whose fumes are conveyed in the vapour or steam, may be used in much greater quantity when applied thus externally and locally, than when prescribed internally. *Fomentations* and *poultices* containing emollient, narcotic, or other medicines, are also efficacious, not merely by the moist warmth they afford, but in great measure by the impression made upon the nervous tissue by the particular medicinal substances they contain. The same remarks apply to medicated warm baths.

233. It is principally for inflammations attended by excessive pain, by much constitutional irritability, by a very frequent and irritable pulse, and depressed vital powers, that the warm and soothing applications now mentioned are required. Hence they are generally appropriate in the specific and asthenic inflammations: and in them especially afford very great relief, particularly when brought in aid of judicious internal treatment and suitable regimen, and employed early in the disease.

234. (*c*) Applications which constringe the expanded capillaries, restore their lost tone, and prevent the stagnation of the blood, or promote the circulation in them, are suitable to certain states of the advanced stages, and to some of the consequences, of sthenic inflammation. They are also appropriate to most of the specific and asthenic phlegmasiæ from their commencement. When the former proceeds to ulceration, and especially if this assume a spreading or phagedenic form, the more energetic astringents, as the various *turpentines* and *balsams*; certain *metallic salts*, particularly solutions of the sulphates of zinc, of copper, iron, &c., of the nitrate of silver, and of the acetates of lead, zinc, &c.; the dilute *mineral acids*; solutions of the *chlorinated soda*, of the *chloride of lime*, and of the *chlorate of potash*; various *vegetable astringents* and *tonics*; *creasote, camphor*, the *vegetable acids*, &c.; are severally beneficial in such circumstances, when suitably prescribed and combined with other appropriate means — in some instances with narcotics, and in others with mucilaginous or albuminous substances, — occasionally in aqueous vehicles, and sometimes in unguents, cerates, &c. It is chiefly, however, when the states or consequences of inflammation just noticed are external or near the surface, or within reach, that applications containing any of these are found useful; yet even when seated in internal surfaces, as in the intestinal and respiratory, they are occasionally beneficial, employed either in the form of draught, pill, and enema, or by means of the inhalation of aqueous vapour partially charged with the fumes of some of them. Although it is chiefly for the advanced stages or consequences of asthenic inflammations that astringent substances are required, yet the early and acute stages are also sometimes benefited by them, however stimulating or irritating they may seem to be. Thus, in scalds, and in certain states of burns, the application of a cloth wetted with spirits of turpentine will generally not merely afford relief, but hasten resolution of the inflammatory action. In such cases it may be truly said with SHAKSPEARE that,

> "One fire burns out another's burning."

235. (*d*) Substances which protect the inflamed surface from the irritating influence of the air, and of the exhalations floating in it, are extremely beneficial in all cases in which the part is abraded or its continuity injured. They are, however, less useful when they prevent the morbid secretion of the inflamed part from being discharged. In most cases, therefore, they should be so employed as to prevent any accumulation of this secretion from taking place, whereby the surrounding tissues might be contaminated. Most of these substances are advantageously made the vehicles of astringent or detergent medicines, thereby diminishing the discharge by constringing the extreme vessels, as well as excluding a chief cause of irritation, and of

the consequent morbid secretion. The principal advantage derived from plasters, cerates, ointments, &c., is owing to the exclusion of the air by them from the abraded or divided surface. In many cases of injury, the fibrinous lymph exuded from the extreme vessels, by coagulating over them, protects them from irritation; and were this natural protection more frequently allowed to remain, and confided in, inflammation would less frequently supervene on these cases, than it otherwise does. The albuminous exudations, formed on superficial ulcerations and inflammations of exposed surfaces, protect them in a similar manner, and dispose them more readily to heal; and if the inflammatory action should at any time be exasperated, so as to give rise to an increase of the morbid secretion or to the production of pus, underneath the protection thus formed, the mischief will often soon subside, and the secretion become absorbed, the parts healing under the scabs, or dried lymph or albumen, covering them. Superficial sores, when protected by the *white of egg*, often heal underneath; and dressings with this substance, by entirely excluding the air, are often more serviceable, in preventing inflammation after incised wounds, and in promoting union, than any other. Strong solutions of the *nitrate of silver*, or of *sulphate of copper*, or *sulphate of zinc*, or other *astringents*, applied to ulcerating surfaces, not only excite the organic nervous tissue, and constringe and give tone to the exhausted extreme vessels; but they likewise coagulate the albuminous portion of the secretion, and thereby protect the part against the iritating influence of the air. They also change the morbid secretion, causing it to assume a more healthy character. Substances which either simply protect a raw inflamed surface, or act in the more complex manner just mentioned, are especially serviceable in cases exposed to the influence of impure air, whether the impurity proceeds from terrestrial exhalations, or from animal emanations, as in the wards of an hospital, or in close, low, or crowded habitations.

236. ii. Treatment of Asthenic Inflammation.— When phlegmasia presents the asthenic form, the treatment should be very different from that recommended above. The states of organic nervous power and of vascular action differ from those attending the sthenic conditions; and as the differences are great, so should the indications of cure, and the means employed to accomplish them, be different. As all the modifications of asthenia depend chiefly upon two classes of circumstances,— upon depressed conditions of the constitution, and weakened functions of the viscera concerned in assimilation and excretion, and upon the sedative, poisonous, or septic nature of the exciting causes,—so all the indications of cure ought to be determined, and the remedies selected, with strict reference to these circumstances. If the local phlegmasia is associated with, or consequent upon, general asthenia or debility, vital power must be augmented by suitable means; otherwise the local disease will more readily terminate unfavourably, especially if it exist in much intensity. If, in addition to general or constitutional adynamia or asthenia, there be impaired excretion, and consequently accumulation of effete elements in the blood, or deterioration of it, not only must vital energy be supported or roused, but also the excreting or eliminating functions must be excited, and means employed which may correct or change the morbid tendency or conditions of the blood; for if these ends are not attained, the structural lesions which the inflammation rapidly induces, instead of being arrested, or terminating in spontaneous resolution, would be rapidly accelerated, and themselves become the source of further local disorganisation, and of constitutional contamination.

237. Asthenic inflammations, whether depending upon original, acquired, or accidental states of the frame, and of the vital organs, or proceeding from specific causes, require a treatment directed more strictly to the conditions of vital power and function — to the constitutional affection and the existing visceral disorder — than to the local disease; and they moreover require this kind of treatment much more than the forms of phlegmasia already considered. In the latter, the constitution and the vital organs have generally been either unimpaired or not materially affected, before the local disease originated and drew them within the circle of its sympathies; in the former, either the constitution, or some important viscus, or both, have been seriously deranged before the inflammation appeared, — this latter being either the consequence of, or an accidental contingency upon, such derangement, and depending upon it in its subsidence, as well as in its appearance. Even when the asthenic forms of inflammation more especially proceed from specific or septic causes, still very much of their local characters and of their constitutional effects depend upon pre-existing states of vital energy and of the assimilating and excreting functions. To these, in their antecedent, as well as in their existing conditions, the attention of both physician and surgeon ought to be mainly directed; and neither the one nor the other will discharge his duties, if he does not connect the forms and changes of the local affection with the constitutional disorder and the visceral derangements, and treat each of them with strict reference to the rest.

238. Although *indications of cure* should not be followed in succession, nor acted upon individually, and without regard to their joint operation,—although attempts at accomplishing one intention, without endeavouring to attain others at the same time, should not be made in asthenic, any more than in sthenic, inflammations,—yet it will be necessary to have just ideas, as to the principal objects to be attained, in order to arrive at a successful issue; and as to the importance and applicability of them severally in the treatment of each particular case. These *objects* or *intentions* should be entirely based upon the characters assumed by the constitutional commotion, by the visceral disorder, and by the inflammation,— the seat and cause of the phlegmasia, and the circumstances immediately connected with the patient, being also taken into account. Upon these, the activity with which each indication of cure should be pursued, and the importance assigned to one or more of them, should chiefly depend. Influenced by these considerations, and by the phenomena and progress of asthenic phlegmasiæ, the physician, in their treatment, will propose to himself —1st, To promote organic nervous power, and thereby to enable the constitution to resist the progress of the local disease; —2dly, To preserve

or to restore the healthy state of the circulating fluids, and the crasis of the blood, by promoting the excreting or depurating functions, and by other appropriate means;—and, 3dly, To assuage the urgent symptoms referrible either to the local malady or to the constitutional affection. The means which most efficiently fulfil the *first* of these intentions, will generally also promote the attainment of the second and third; and whatever has the effect of accomplishing the *second*, will also most materially advance the other indications.

239. *A. The constitution will generally be enabled to resist the local progress of the malady*, by whatever increases the tone or energy of the organic nervous system, through the medium either of the digestive canal, or of the respiratory organs, — by means of appropriate tonics and stimulants, and by a dry, pure, and temperate air, duly renewed. All asthenic inflammations have a tendency to spread or to extend themselves with a greater or less rapidity, and to terminate unfavourably,—the changes that successively arise, tending to gradual disorganisation, or to more immediate sphacelation. Unless under the influence of agents which rally the constitutional powers, they seldom or never show a disposition to spontaneous resolution, as often observed in sthenic phlegmasia. The only exceptions to this rule are met with in those asthenic inflammations which constitute a part of specific constitutional maladies; and these are mere symptoms, or parts only, of these maladies, and are generally co-ordinate with and dependent upon them, in their rise, progress, and decline. This tendency to spread, and to give rise to a succession of unfavourable changes, constitutional as well as local, requires agents possessing powers of sufficient activity to meet the intensity of the disease. As this tendency depends upon depressed organic nervous energy, and deficient vascular tone, as shown above (§ 58.); and as the permanent fluidity of the effused fluids, and their infiltration, and contamination, of the surrounding tissues, depend upon these pathological states; it is obviously requisite to employ such means, as attentive observation and enlightened experience have proved to be most efficient in removing them. All parts which are the seat of asthenic inflammation rapidly lose their vital cohesion or tone; and this loss is participated in, not only by the extreme vessels, giving rise to a copious morbid effusion, but also by the tissues affected. The chief pathological conditions, from which all the consecutive changes have been shown to proceed (§ 162. *et seq.*), manifestly require an energetic recourse to those means which will enable the constitution to resist the progress of the local mischief. Where cellular or adipose tissues are implicated, the extension of disease, and even of disorganisation, will be rapid, if organic nervous energy be not promoted, and if vascular action in the seat of inflammation be not changed, by suitable remedies. In such cases, the constitution must be enabled, as John Hunter ably contended, to form coagulable lymph, either in, or around, the inflamed part, — or, in other words, to change the fluid and often septic matter effused in the areolæ of the tissues, that extends the mischief by infiltrating and contaminating them, into coagulable lymph or albumen, whereby these areolæ may be rendered impervious to the more fluid part of the effused matter, and the progress of the local malady may be more readily limited.

240. The *principle* of treatment in asthenic inflammations being established, the *means* by which it may be most successfully carried out in practice will be readily found; although the application of these means, appropriately to the varying phases of individual cases, requires great discrimination and care. In the truly asthenic forms of phlegmasia, the principle contended for must be acted upon with decision, and without wavering or temporising. In the treatment of them, doubt or hesitation is fraught with danger; and proceeding, as either generally does, from ignorance of the true source and relations of the local malady, there will be every reason to fear that much of both positive and negative wrong will be further perpetrated. The ignorant are usually presuming; and the half informed, self-sufficient. In other professions and avocations, the evils produced by both are comparatively trivial; but, in the practice of medicine, their consequences are of fearful and immeasurable importance to humanity. I have seen numerous cases of asthenic inflammation die in succession, without the occurrence of a single instance of success to lull the suspicion that true principles of practice had not been adopted; and yet the same principles were blindly pursued in each successive case. In a country where the most trivial invasion of the rights of property is visited by the most condign punishment, human life may be sacrificed to an extent that more than rivals both the pestilence and the sword, by ignorant pretenders to medical knowledge — by the totally uneducated as well as by the half instructed,—and not merely with perfect immunity from punishment, but actually with the protection of the government, that protection being virtually the most complete for those whose ignorance is the greatest! This sacrifice of human life, be it further recollected, is constant and unceasing — not occasional only, or at long intervals, as that caused by epidemics, pestilences, and wars. — It was said, upwards of two hundred years ago, by a celebrated Archæologist (Sir H. Spelman), "that whilst every thing else had risen in nominal value in England, the life of man had become continually cheaper." What would he have said, had he lived in the present day?

241. The *means*, by which the indication or practical principle above contended for is to be fulfilled, must necessarily vary with the circumstances of the case; but the decoction of *cinchona*, or the infusions of *cascarilla* and of *gentian*, &c. with the *alkaline carbonates* (F. 381. 385. 387, 388. 445. 869.), are generally beneficial, especially when aided by warm aromatic tinctures or spirits. When the pulse is very quick, soft, and weak, and when the patient is physically and morally depressed, the *chlorate of potash*, *serpentaria*, or other stimulants, may be added to the above (F. 415—417. 437—439.). In these cases, *camphor* in full doses, the preparations of *ammonia*, and *capsicum*, or other spices and aromatics (F. 845. 852.), may likewise be prescribed. In all asthenic inflammations, the excretions, and the fluid effused in the diseased tissues, are more or less acid,—a state which is most readily corrected by the alkaline carbonates, conjoined with tonics and aperients. In many cases,

however, the preparations of *chlorine*, particularly the *hydrochloric acid*, the *hydrochloric æther*, and *chlorinated soda*, prescribed with tonic vegetable infusions or decoctions, and with camphor, aromatics, &c., are equally beneficial with the foregoing (F. 847, 848.).

242. *B.* But, in order to promote the powers of life, and thereby to enable the vessels of the diseased part to form coagulable lymph, whereby the progress of mischief may be arrested, it is necessary, not only to excite the organic nervous system, but also *to depurate and to correct the circulating fluids by appropriate medicines.* This intention will be fulfilled chiefly by promoting the excreting functions by mild *purgatives*, conjoined with *tonics* and *aromatics*, as the compound *infusions of gentian and senna* with the alkaline salts (F. 266.), the compound *decoction of aloes* with warm aromatic tinctures or spirits, or the infusions of *rhubarb* and *cinchona* (F. 55. 387. 433.), or other similar remedies (F. 53. 215, 216. 872.). In the intervals between the exhibition of these, tonics and stimulants should be selected, and given in doses and combinations suitably to the seat and urgency of the disease. If the purgatives just mentioned act insufficiently, a dose of oil of turpentine and castor oil (about half an ounce of each) may be taken on the surface of milk, or of any aromatic water (F. 216.), and enemata containing the same oils (F. 135. 151.) administered according to circumstances. If the biliary secretion be suppressed or interrupted, *calomel* or PLUMMER's pill may be given at bed-time, with *camphor;* and a draught containing the oils, or either of the above purgatives, may be taken in the morning. The combination of the mild alkaline salts, or of the chlorate and carbonate of soda (F. 439.), with the foregoing tonic or other medicines, will generally correct the circulating fluids, diminish the contaminating influence of the matter effused in the seat of disease, and further promote the fulfilment of the present indication.

243. *C.* From the commencement of the treatment, it is often requisite *to mitigate the more urgent local and constitutional symptoms.*—*a.* The remarkable pain and tumefaction of the inflamed part are best relieved by anodyne fomentations, by warm bread and water poultices, or by the local application of simple or medicated steam. In the more complete forms of asthenic inflammation, no advantage will accrue from the application of leeches to the inflamed part; although a recourse to incisions of the integuments, as recommended by Mr. A. COPLAND HUTCHISON, and others, will often be of service, when cellular and adipose parts are the seat of disease, and the tension is very great. I have seen also the application of a cloth moistened with oil of turpentine have a very remarkable effect both in mitigating the pain, and in lessening the tension and tumefaction. It should be applied warm, and covered with wash-leather or oil-skin to prevent evaporation and cold. In several cases, where the swelling has been most extensive, — the whole limb to the trunk having been affected,—I have seen it subside very quickly after a decided recourse to the internal and external treatment here recommended. In most of these cases, the tone of the vessels has been rapidly restored, congestion of them removed, and the effused fluid absorbed, without coagulable lymph having been formed, or suppuration having supervened, excepting in some instances at the point of injury, or where the disease originated. When this treatment is early resorted to, not only is the progress of the disease arrested, but also much of its more immediate effects is removed, without the lesser evil, the formation of fibrinous lymph, for which JOHN HUNTER contended, having taken place.

244. *b.* At advanced stages of asthenic phlegmasia, more frequently, and even at early periods occasionally, excessive *pain* and general *irritability* call for a prudent yet decided recourse to *narcotics*. In these cases, a lowering treatment will neither mitigate the pain nor diminish the other symptoms, but, on the contrary, increase them all, and render still more rapid the already quick and irritable pulse. Here *opium*, or the acetate or hydrochlorate of *morphia*, or *hyoscyamus*, in large doses, must be resorted to. But these ought always to be conjoined with *camphor* and some of the *aromatics* or *spices*.— When *delirium* appears in the course of asthenic inflammation, depressing remedies are generally injurious; but the narcotics just named, and combined as now advised, will be of the greatest benefit, particularly in conjunction with the restorative treatment above recommended, and after the excretions have been duly evacuated by appropriate means.—(See art. DELIRIUM.)

245. *c.* When asthenic inflammations are attended by general *vital depression without re-action* (§ 62.), the most energetic stimulants, tonics, and restoratives are necessary; and if delirium supervene, camphor, ammonia and opium, with warm aromatics, should be freely exhibited.

246. *d.* When organic nervous or *vital power is depressed, although much general vascular excitement exists* (§ 63.), the pulse being rapid and weak, similar means to the above are requisite, but in less energetic doses. Camphor, with the narcotics already advised and aromatic spices, mild stomachic purgatives, occasionally aided by a draught and an enema containing turpentine and castor oils, are also most efficient remedies.

247. *e.* In cases characterised by *depressed vital power, acute nervous sensibility, and cerebral disorder* (§ 64.), the means just recommended are urgently called for; but the narcotics and camphor should be prescribed at an early period of the disease, and in large doses. The effusion of tepid or warm water on the head, according to the temperature of the part, may be employed. Medicated vapour or warm baths may also be tried, and medicated steam (§ 232.) may likewise be applied to the local malady.

248. *f.* When there are *excessive irritability, acute pain, and vascular excitement* (§ 65.), the internal and external treatment just prescribed, but modified according to the stage and particular features of the disease; a combination of camphor calomel, and opium; stomachic aperients, with the alkaline salts, and an occasional recourse to turpentine and castor oil, in the form of draught or enema; are chiefly to be relied upon.

249. *g.* Great *irritability of stomach* may occur at an earlier or later period of asthenic inflammations, when attended by any of the forms of constitutional commotion just referred to. When this is the case, every endeavour must be used to allay it. Warm aromatics, or spices and stimulants, with small doses of opium, will generally have this effect in the less urgent cases; par-

ticularly when aided by the assiduous application of the warm turpentine epithem over the region of the stomach, and by the administration of stimulant and antispasmodic enemata. In such circumstances, those articles which are most grateful to the stomach should be selected, and every thing of a depressing nature avoided. Effervescing medicines are seldom useful, especially if this very unfavourable symptom occur at an advanced period of the disease. More advantage will accrue from small and frequent doses of ammonia, camphor, capsicum, and other warm aromatics or stimulants, — from small quantities of burnt brandy, — from strong and highly spiced negus, — and from other restoratives of small bulk, — than from cold relaxing fluids. I have seen much benefit derived in these cases from moderate doses of créasote, or of cajuput oil, in suitable vehicles, or in the form of pills made with any absorbent substance.

250. *h.* When disorganisation of the inflamed part has commenced, or is advanced, *local means* of an energetic kind may be prescribed if they can reach the part in any way; if they cannot, the constitutional treatment, aided by suitable diet and regimen (§ 260.), and by a pure, dry air, must be energetically but carefully enforced. As to the topical applications which may be prescribed in these circumstances, some incidental observations have been already offered; but it may be further stated, that those substances which *constringe* or *impart tone* to the affected vessels and tissues should be employed, and that those which possess this as well as an *antiseptic property* in the most marked degree, should be preferred. Strong decoctions or infusions of cinchona, or oak barks, the terebinthinates, the solution of chlorinated soda, or of the chlorate of potash, or of the chloride of lime, or créasote, may be severally employed in the form of either lotion or injection, or on the surface of warm poultices, or in any other mode more appropriate to the peculiarities of the case.

251. *i.* During the treatment, especially of the advanced stages of asthenic phlegmasia, the *absorption of the morbid matter* from the seat of disease, into the circulating fluids, ought to be prevented by every possible means. This object can be obtained only by giving a free exit to whatever of this matter may have accumulated, and by preventing any collection of it from taking place. The internal treatment, which I have advised, will also have a most decided influence in preventing the absorption of it, and will enable the powers of life to resist whatever morbid impressions it may make in the seat of disease. The marked influences of all depressing agents in promoting the absorption of morbid fluids, and the powers of tonic and restorative means in preventing absorption, and the consequent contamination of the circulating fluids, as well as in enabling the constitution to resist the natural tendencies of these fluids and to throw them out of the œconomy, have been fully shown in the articles ABSORPTION (§ 15. *et seq.*), ABSCESS (§ 62.), BLOOD (§ 143. 157. *et seq.*), CELLULAR TISSUE (§ 35, 36.), and VEINS — *Inflammation of*. The constitutional and local treatment fully described when discussing *Typhoid* and *Putro-adynamic* FEVERS, *Diffusive Inflammation of the* CELLULAR TISSUE, and GANGRENE, is generally suitable to asthenic inflammations.

252. iii. TREATMENT OF INFLAMMATIONS INTERMEDIATE BETWEEN THE STHENIC AND ASTHENIC, &c. — Although inflammations generally present characters belonging more especially to the sthenic or asthenic forms, yet they occasionally present features appertaining to both, and consequently they require a somewhat different or modified treatment from what has been here assigned to each of the principal forms. Like all febrile diseases, inflammations also change their types and characters, under the influence of *climate, season,* and *epidemic constitution;* and hence, at particular periods, they not only present *sthenic* or *asthenic forms*, but also *transition*, or *intermediate, states.* Nor ought it to be forgotten, that these transition or intermediate states, as well as the more truly asthenic forms, are either so dependent upon, or associated with, certain conditions or affections of the constitution, — often of the organic nervous and circulating systems, — as to impart to the local malady many of its peculiar features. This is very manifestly shown in those inflammations which I have denominated *specific*, as arising from certain specific, or infectious, or poisonous causes, — in *erysipelas, puerperal inflammations, dysentery, small-pox, scarlatina, measles, syphilis,* &c.

253. *A.* Nor should it be overlooked, particularly in the treatment, that numerous morbid impressions made upon the œconomy, more especially by *epidemic constitution* and by *terrestrial exhalations,* modify remarkably all inflammations, and deflect them more or less from the sthenic type, to which I have sufficiently directed attention. These influences, therefore, however operating, must always be kept in view, in connection with other predisposing and exciting causes. The prevailing epidemic constitution is often sufficiently evident in its effects, however obscure in its origin and nature. The attentive observer will seldom fail of recognising it, even in its earlier appearances, particularly if the circumstances, to which I have already alluded (§ 191.), be observed.

254. *B.* The influence of *malaria* or of *terrestrial emanations* on inflammations is also important, although it is less observable in this country than in many others. In the southern countries of Europe, Asia, and America, and in many intertropical regions, malaria, by its effects upon the constitution, imparts to inflammation more or less of an asthenic or adynamic character, accelerating its course, or rendering its consequences most serious. In the less intense forms of inflammation, and particularly in their more chronic forms, the constitutional affection assumes either a *remittent* or *intermittent type.* In the former case, the influence of the paludal effluvia is often overlooked, or insufficiently estimated: in the latter, the local affection too frequently escapes detection, or is even never inquired after, the form of the attendant fever alone attracting notice.

255. *C.* In the *white races* of the species, and in the inhabitants especially of northern and temperate regions, the sthenic form of inflammation, and those states of the disease which more nearly approach it, most frequently occur. But in the *black* and *dark-skinned races,* inflammations either assume, or rapidly pass into, more or less asthenic forms. The mode of living is another circumstance which should be viewed in connection with the variety of species in which these diseases may occur, and which is of equal importance with it,

in the treatment of this class of maladies. Owing to the peculiarity of organisation possessed by the dark races, and to the forms which inflammations consequently assume in them, vascular depletions and other evacuations more readily exhaust the vital or constitutional powers, and are much less beneficial in the treatment of these diseases, than in the white races. Hence they should be most cautiously employed in these former varieties of the species, even although the phlegmasia may present, at its commencement, a predominance of the sthenic characters; and when it appears in an unequivocally asthenic form, means energetically tonic and restorative are especially requisite.

256. *D.* Much of this intolerance of depletions and lowering remedies, in the treatment of the inflammatory diseases of the dark races, may be attributed to their low or *abstemious diet*, and to their living chiefly on *farinaceous substances*. Although the constitution and modes of living of these races thus impart a certain character to many of their maladies, and especially to those under consideration, yet they also bestow upon them a much greater immunity from inflammations, than is possessed by the white and more highly fed variety of the species. Persons who live chiefly on animal food, and particularly on simply dressed or underdone meats, are much more liable to sthenic inflammations, and require much more copious depletions and alvine evacuations for their cure, than those who use vegetable food, or animal substances which have undergone great changes by elaborate or repeated cookery.

257. As these states of inflammation, which may be viewed as intermediate between positively sthenic and asthenic conditions, vary with these and other circumstances, so the treatment must necessarily be varied accordingly: but the several respects, in which variations should be made, cannot be stated with precision; they ought to be adopted conformably with the deductions, as to existing pathological conditions — local and constitutional — formed by the practitioner at the time of prescribing for them. Every thing must depend upon his pathological knowledge and acumen, and upon his practical resources, appropriately applied to each case.

258. *E.* The treatment of *specific inflammations* and associations of the phlegmasia with other maladies implicating the constitution or the principal viscera, especially those just named (§ 252.), requires no remark at this place. They present every intermediate feature between the sthenic and asthenic forms above described, according to the constitution and age of the patient, and to external or internal agents, existing epidemic constitution, and other circumstances by which his frame may have been, or is at the time, influenced; and they consequently require an application of the principles of practice, as well as appropriation of individual means, conformable thereto. But these topics will be found as fully discussed as the nature of the subject will permit, in the articles devoted to these *specific inflammations*, as well as in those on DYSENTERY, ERYSIPELAS, *the Complications of continued* FEVERS, &c.

259. iv. *The treatment applicable to* THE CONSEQUENCES *of the different forms of inflammation*, either has already been noticed in the foregoing observations, or has been fully considered in the separate articles devoted to the chief of these consequences, particularly ABSCESS, GANGRENE, INDURATION, SOFTENING, &c.

260. v. The DIET and REGIMEN ought to be strictly *antiphlogistic*, in the *sthenic forms* of phlegmasia. The *food* taken in the slighter and more chronic cases should be mild, farinaceous, and in small quantity. The *beverages* or *drink* ought also to be cooling and diluent (F. 588. *et seq.*). Perfect quietude of body and mind should be enforced, as tending most materially to keep down vascular action, to prevent the exhaustion of vital power, and to promote the operation of the medicines employed.

261. When inflammation assumes, or passes into, an *asthenic form*, it will be necessary to support the powers of life by a restorative diet and regimen, as well as by the medical treatment recommended (§ 236. *et seq.*). But in such cases, the digestive organs are always remarkably weak, are incapable of assimilating much food, and are readily disordered by whatever is difficult of digestion. The stomach should therefore be kept in humour, by allowing that only to be taken which is craved for or most relished. Generally, in the more asthenic cases, small quantities of warm or highly seasoned soups or broths, as beef-tea, gravy, or Mulligatawny soup, with boiled rice, &c., warm jellies, with old sherry, and similar articles, may be taken. If vital depression be great, warm and highly-spiced negus, or mulled wines, and even champagne, may be freely allowed. In many instances, when there is much thirst, brisk bottled stout, seltzer-water with wine or milk, spruce or ginger beer, &c., may be given, and may even be made the vehicle of warm restorative medicines; but they ought not to be given until their temperature is raised somewhat above that of the surrounding air, nor should they be taken in too large a quantity at one time. In this form of inflammation especially, the patient should respire a mild, dry, and pure air. The varying phases of the disease — local and constitutional — ought to be carefully observed throughout; and whatever may occur of an unfavourable character, instantly met by energetic means.

CLASSIF. — 1. *Class*, Febrile Diseases; 5. *Order*, Fluxes (*Cullen*). 3. *Class*, Sanguineous Function; 2. *Order*, Inflammations (*Good*). III. CLASS, II. ORDER (*Author*, see *Preface*).

1. DEFIN. *Lassitude; pains in the head, loins, or limbs; chills, horripilations and coryza, followed by cough, by defluxions from the respiratory passages, by fever of a nervous or adynamic character and by anxiety at the præcordia, or pains about the margins of the ribs; the disease attacking a number of persons at the same time, and often passing into asthenic inflammation of the respiratory surfaces or organs.*

2. I. HISTORY.—*Influenza*, or *Epidemic Catarrhal Fever*, has been noticed by many medical writers since the revival of learning in Europe; and, although presenting on all occasions the same general features, yet it has assumed somewhat varied characters with the several circumstances connected with its appearances. The seasons, the weather preceding or during its visitations, the climate, and the locality, have, doubtless, slightly modified some of its phenomena; yet it has generally presented nearly similar features in very different seasons and situations. Indeed, whatever diversity may have existed in its several visitations, has been referrible rather to the epidemic itself than to other causes.

3. The earliest recorded occurrences of influenza were in the years 1239, in 1311, 1323, 1327, 1358, 1387, and 1403. VALESCO of Tarentum was a witness of that of 1387; and he remarks respecting it, that scarcely one tenth of the population escaped the disease, the aged chiefly dying of it, and rheumatic affections often following it. The most successful means of cure consisted of pectoral decoctions and sudorifics. It appeared again in 1411, 1414, 1427, and 1438. CARLI, the historian of Verona, describes this last to have been general throughout Italy, and fatal to the aged and to young children. MEZEREY, the French historian, notices the prevalence of influenza in France, in 1482. TORRELLA, in his history of Italy, states that an epidemic catarrh prevailed throughout Italy and Spain in 1505, "qui paucis pepercit, senibus maxime, cum raucedine, gravedine, molestâ tussi, destillationibusque per superiora, comitante febri."—The historian DE THOU mentions the appearance of a similar epidemic in 1510; and SENNERT remarks respecting it—"in omnes ferè mundi regiones debacchata, cum febre, summâ capitis gravitate, cordis pulmonumque angustiâ atque tussi; quanquam multò plures attigit quàm jugulavit." (*De Abd. Caus. Rer.* lib. ii. cap. 12.) A similar epidemic pervaded Europe in 1557, and is described by RIVERIUS, SCHENCK, and others. It presented the same symptoms as those observed in the recent visitations of the disease. MERCATUS (*De Int. Morb. Cur.* lib. i. c. 43.) observes, that the Spanish physicians were greatly perplexed as to the treatment of this epidemic, for bloodletting and purging were of no service, but even injurious in many cases; and VALLERIOLA (*Soc. Med. Comm. Append.* cap. ii.) states that it possessed the same characters in France — bleeding and purging being injurious, but demulcents and expectorants beneficial. The epidemic of 1578, described by BALLONIUS or BAILLOU, and which has been noticed by OZANAM and others as influenza, was evidently hooping-cough — inasmuch as it attacked children chiefly, and as the paroxysms of cough, which occurred at considerable intervals, were attended by vomiting of large quantities of a glairy fluid. That, however, which occurred two years later (in 1580), was certainly influenza. MERCATUS describes not only the catarrhal symptoms, but also the pains in the head, back, limbs, and about the false ribs, usually attending this disease. He observes that bloodletting was often fatal —"Quo profectò, factum fuit, ut plures interficerent imprudentes et imperiti medici quàm mali sævitia et inclementia." SENNERT (*Opera*, lib. iv. c. 17.) remarks of this epidemic, that, although generally prevalent in Europe, but few died of it, excepting those who were the subjects of old pectoral or visceral diseases, or who were improperly blooded. Similar observations are offered by WIER, ZACUTUS LUSITANUS, CAMPANA, RIVERIUS, &c., who state that this epidemic prevailed over the whole globe, and in Europe, chiefly in April and May. FORESTUS prescribed a small bloodletting at the commencement of the disease, but confined this practice to the young, strong, and plethoric.

4. The epidemics of 1596, 1597, and 1617 offer nothing worthy of remark. That of 1627 was altogether the same as the one just noticed. The influenza of 1658 is fully described by WILLIS, as he observed it in London, in April, May, and June. Many aged, infirm, and delicate persons were cut off by it; pulmonary congestions, bronchitis, and pneumonia having manifestly,

from his description, been complicated with it. He treated it by moderate bloodletting, in the young and robust, and by diaphoretics and pectoral medicines. The slighter cases recovered spontaneously after a copious perspiration. This disease appeared again in Continental Europe in 1663.—Bartholin, Sylvius de la Boe, and Ettmüller describe the epidemic of the summer of 1669 to have appeared after a severe spring, and variable weather at the beginning of summer. They employed chiefly sudorifics and pectoral medicines in its cure.

5. The epidemic catarrh of the autumn of 1675 was general throughout Europe. Rayger and Peu state that it appeared after a very rainy summer, and that it was preceded by thick mists and fogs, and inconstant weather. Puerperal females in many cases aborted, and others suffered menorrhagia. When the loss of blood was considerable, dropsy, debility, and prolonged convalescence ensued. This epidemic did not prevail in England until the following year. It is described by Sydenham and Ettmüller. The disease commenced with pains in the head, loins, and limbs, with great prostration of strength, cough, pains in the sides and points of the ribs, and occasionally bloody expectoration. Sydenham remarks that the pulmonary affections were merely symptoms of the epidemic aggravated by the cough, and sometimes by a too stimulating treatment and regimen. He viewed the disease as resulting from the action of a cold humid air upon the skin; the fluid secreted by this emunctory being thrown in upon the system, and exciting fever, cough, and disease of the lungs. He directed his treatment chiefly to the fever, and prescribed moderate bloodletting, diaphoretics, laxatives, diluents, and emollients. Large depletions were injurious; and evacuations prolonged the complaint in hypochondriacs and in hysterical females, and rendered the convalescence tedious. Of the less extensive epidemics of 1691, 1695, and 1699, it is unnecessary to take any notice; and those which appeared early in the eighteenth century need only to be slightly mentioned.

6. The influenza of 1729 and 1730 appeared after severe and changeable weather at the beginning of 1729; and traversed the whole of Europe during summer, autumn, and the commencement of winter. It varied in its general characters and complications in different countries, and at different seasons. It was frequently not ushered in by chills or rigors, but by lassitude, depression, headach, pains in the loins and limbs, oppression at the chest, anxiety or pain in the epigastrium, coryza, severe cough, sore-throat, and heat of skin, the pulse being quick and irregular. Swellings of the parotids, or of the tonsils, were not infrequent; and the pulse was often remarkably small and weak. In other cases, horripilations, vertigo, and rigors ushered in the disease, which sometimes assumed a severe character,—delirium frequently supervening. The most violent cases occurred in low, humid, close, or miasmatous localities, and were complicated with pneumonia, pleuro-pneumonia, or with bronchitis; and the fever, in these situations especially, presented somewhat of an adynamic or malignant character. When the complaint was simple, it often terminated from the fourth to the seventh day by epistaxis, or by a slight expectoration of blood, or by the hæmorrhoidal or menstrual flux. In the more complicated cases, congestions of the brain or lungs, and dropsy of the chest, frequently occurred; chronic bronchitis, consumptions, and various other diseases appearing as their sequelæ. It was most dangerous to the aged, and to those who had previous disorder of the respiratory organs. The treatment consisted chiefly of a moderate bloodletting at the commencement of the disease, in the young, strong, and plethoric, in pregnant females, and in the complications with congestion of the brain, or with inflammation of the lungs or pleura; of diaphoretics, diluents, and diuretics; and of mild purgatives followed by anodynes, demulcents, and emollients. (Hoffmann, Beccaria, Morgagni, &c.)

7. The catarrhal epidemic of 1733 appeared in some countries as early as the preceding December, and in some places assumed a more inflammatory character than in others. The head was frequently affected, and hæmorrhages from the respiratory surfaces sometimes occurred. Children and young persons were more frequently attacked than in the influenza of 1729; but the aged, and those already the subjects of visceral disorder, were most severely and dangerously seized. The plethoric and sanguine often presented inflammations of the throat and lungs; and the bilious experienced severe pains in different parts. The intemperate suffered greatly from gastric disorder. Dropsy of the chest often supervened at an advanced stage, or as a sequela of the disease. Bloodletting was injurious, unless in the complications with pneumonia, or pleuro-pneumonia; and even in these it often proved hurtful, when carried too far, or exclusively trusted to. Emetics, mild purgatives, diaphoretics, and demulcents, with diuretics, and afterwards tonics and antispasmodics, were found most generally useful. The same epidemic, as it occurred in the South of England, was described by Huxham, who notices the disposition to perspiration, which appeared about the second or third day and abated the fever, proving a crisis to it about the fourth in the milder cases. He found emetics of great benefit, when there was nausea or biliary disorder. After bleeding, in the pulmonary complications, he prescribed expectorants. His treatment, in other respects, was similar to that already mentioned.

8. Huxham has described the influenza of 1737 to have commenced with chills, headach, coryza, repeated sneezing, and pains in the face, loins, or limbs. Copious defluxions from the nostrils and respiratory passages, severe cough, difficult expectoration, oppression at the præcordia, &c., generally followed. Sore-throats, swellings of the parotids or submaxillary glands, severe pains in various parts, and sciatica were often also complained of—the symptoms varying much with individual constitution, &c.—Many experienced only slight febrile disturbance, which terminated in a moderate sweat; and in others the disease passed into a dangerous peripneumony; and the severer cases were generally followed by great prostration of strength, by consumption, pains in the limbs, or obstinate rheumatism. The treatment was nearly the same as that employed by him in the preceding epidemic; but he found that bloodletting could be carried somewhat further than in it, particularly in the complicated cases. Blisters, diaphoretics, and expectorants were generally pre-

scribed. For the removal of the rheumatism which followed this disease, he employed calomel with purgatives and antimonials.

9. The catarrhal fever of 1742 followed a most severe winter; north-east winds having prevailed for nearly five months. Its characters, were in no respects different from most of the epidemics already noticed. The most severe cases presented signs of adynamia, or even of malignancy, particularly in the aged, debilitated, cachectic, or previously diseased. In the simple form of the distemper, bloodletting and evacuations were injurious; and diaphoretics, expectorants, and diuretics were beneficial, in this and in other forms. But, when the respiratory organs became inflamed, vascular depletion, cautiously employed, was requisite, particularly early in the disease. In this epidemic, paregorics, oxymel of squills, and a gentle emetic at the commencement of the complaint, or immediately after the bleeding, when this was required, were generally employed by Huxham, Sauvages, and others.

10. The epidemic of 1762 pervaded nearly the whole of Europe, between the months of February and July. Descriptions of it have been left by De Maertens, Baker, Gilchrist, Watson, and others. It proved very fatal to the aged, the asthmatic, and previously diseased; and pregnant females often suffered abortion or premature labour when attacked by it. Gilchrist, with much justice, viewed this, as well as other epidemics of the same kind, as a fever, *sui generis*, attended by catarrhal symptoms. The course, complications, consequences, and treatment of this influenza differed in nothing from those which preceded and followed it.

11. The catarrhal epidemic of 1775 pervaded Europe, and, like several visitations of the same kind, was not confined to the human species, but affected also the lower animals—often commencing with them. It broke out during a dry and warm summer, following a mild and very dry spring. This was the first epidemic that received the name of *influenza*, it having been generally imputed in Italy to a peculiar aërial influence. It commenced with reiterated chills, lassitude, coryza, sneezings, headach, and wandering pains in the chest, loins, and limbs, followed by fever with incessant cough, copious defluxion, sore-throat, hot skin, a quick soft pulse, pale turbid urine, and vertigo or slight delirium. About the third or fourth day, copious perspiration, hypostatic urine, and free bilious evacuations often took place, and proved critical. It required the same treatment as other preceding epidemics; and when neglected, often passed into asthma, chronic bronchitis, and consumption.

12. Of the epidemic catarrhs, which have occurred from 1775 to 1833 — namely, in 1782, 1789, and 1803 — I shall notice only that of 1782. It appeared in Great Britain between the end of April and the middle of June, and attacked about four fifths of the population. It was least prevalent and mildest in children. It was most severe in the aged, the asthmatic, and the previously debilitated or diseased; and, except these, but few died of it. Like other epidemics of this kind, it seldom continued longer than six weeks in a place. The treatment was similar to that adopted on former occasions. Bleeding was required only when symptoms of pleuritis or pneumonia appeared. Gentle emetics and mild purgatives were useful early in the disease—the former chiefly when the expectoration was difficult. When the expectoration was too profuse, bark or other tonics were required. Where the cough continued long and obstinate, opiates and change of air were most serviceable.

13. From the foregoing brief epitome of some of the most remarkable epidemic catarrhal fevers upon record, it will be observed, that they have been all essentially the same in character, and that they required the same principles of treatment. Certain differences, however, existed, not only in those of which I have made mention, but also in most of those to which I have thought it unnecessary to refer. In some, an inflammatory diathesis seemed more apparent than in others; but when inflammatory complications occurred, they always presented more or less of the asthenic diathesis; or the accompanying, and indeed the primary, fever presented more of a nervous or adynamic, than of an inflammatory form. The constitutional disturbance generally preceded the inflammatory complications; such complications arising out of predisposition, of previous disorder, or of accessary causes. In some epidemics, children and young persons were more affected than in others: but in all, the aged, the asthmatic, the debilitated, and those subject to disorders of the respiratory organs were most seriously attacked. Although the disease was most prevalent between the ages of fifteen and fifty, as in most other epidemic fevers, yet it was least dangerous or fatal at this period. Some of the epidemics differed from others in the presence or severity of the pains in the head, chest, back, or limbs. In some, particularly, the pains assumed the form of a rheumatic complication, which continued after the febrile and catarrhal symptoms had been removed; in others, they seemed to depend upon biliary colluvies, or collections of morbid bile in the biliary apparatus. In some, also, the complication was very generally bronchitis, or pneumonia, or pleuro-pneumonia — whilst in many, sore-throat, with or without swelling of the adjoining glands, or gastric disorder, was more or less evident. Lastly, some epidemics, although almost universal, were comparatively mild; and others were both severe and fatal; the fatality proceeding chiefly from the severity, or extent of the complications, and from previous disease.

14. The *sequelæ* of the several epidemic catarrhal fevers, of which any satisfactory accounts have been left to us, were nearly the same as observed in recent times. These consisted chiefly of chronic bronchitis; of pulmonary consumption; of hæmoptysis; of serous effusion in the thoracic cavities, consequent upon congestions of the lungs, or of asthenic inflammation of the serous surfaces in this cavity; of rheumatic and neuralgic affections in various parts; and of functional disorder of the digestive and assimilating organs.—In some of the epidemics, and in that of 1837, sciatica was a not infrequent remote sequela of the disease. The *treatment* which was found most appropriate in former epidemics will be further referred to hereafter.

15. II. Symptoms of Influenza.—The account which I shall give of influenza is derived from an extensive observation of its pathology and treatment during the epidemics of 1833 and 1837

—the two most severe visitations of the disease in this country upon record, and especially in London. In both these the distemper was either *simple* or *complicated.*—*A. The simple form* of influenza, was most frequent in the young and middle-aged, and the previously healthy; and usually commenced with chilliness, rigors or horripilations, lassitude, general depression or anxiety, gravedo and headach, followed in some hours by heat of skin, coryza, sneezing, fulness and tenderness of the eyes, soreness of the throat, hoarseness, cough, pain of the back and limbs, loss of sleep, and considerable fever. The cough was generally attended by more or less soreness of the chest, hurried respiration, slight dyspnœa, either pain or a tenderness and bruised sensation at the diaphragmatic margins of the ribs and epigastrium, and wandering pains in the trunk, especially about the sides. Nausea, loss of appetite, sometimes vomiting, costiveness, seldom diarrhœa, and a white, slightly coated, or mucous appearance of the tongue, were also present. These symptoms continued for 24, 36, or 48 hours; the cough being dry, and aggravating the sense of soreness, and the pains about the chest. Afterwards expectoration became more abundant and easy; the skin softer and moister; and the pain of the head or about the frontal sinuses, and in the chest, back, or limbs, less severe. The pulse was generally quick, sometimes a little sharp, usually soft and weak: but it was often irregular, or very changeable and uncertain. As the symptoms became mitigated, about the third, fourth, or fifth day, the perspiration became more abundant, and the urine deposited a copious sediment: yet the cough frequently continued severe and obstinate, and the consequent debility was much greater and more prolonged than the severity or duration of the disease seemed to warrant. In the more severe cases, these symptoms were generally very prominent, and the febrile phenomena fully developed, transient delirium even occurring; but in the slighter cases, several of them were not very remarkable. In this form of the disease, the chest sounded clear upon percussion, and respiration was clear and vesicular, no morbid râle being heard on auscultation; but, as the complaint proceeded, a slight mucous râle was sometimes present.

16. *B.* The COMPLICATIONS, or prominent affections of influenza, were chiefly—(*a*) a peculiar inflammatory condition of the throat and pharynx; (*b*) severe gastric disorder;—(*c*) bronchitis;—(*d*) a specific pneumonia, or pleuro-pneumonia;—(*e*) tubercular phthisis;—(*f*) a form of pleuritis;—(*g*) rheumatism;—(*h*) disease of the heart and pericardium;—and, (*i*) severe adynamic or nervous fever. The frequency of the occurrence of these affections in a predominant form was nearly in the order in which I have enumerated them.—*a.* The *inflammatory state of the throat and pharynx* was very frequent, but sometimes slight. It was always of what has been usually termed an erythematic or erysipelatous kind, but more correctly asthenic or spreading; and attended, as it proceeded, by more or less of a fluid discharge, which served to increase the quantity of matter thrown off at each fit of cough. In the severer cases, this state of inflammatory irritation was accompanied with some swelling; and in many cases, the affections of the bronchi, and of the upper portion of the digestive mucous surface, seemed only the extension of the disorder of the throat and pharynx to these parts. This affection of the throat generally subsided in two or three, or at most five or six, days, after a more or less copious discharge from the affected surface, and sometimes after the extension of disease to the gastric or bronchial surfaces—or rather, after the disorder of the latter had become more manifest.

17. *b. Severe gastric disorder* was indicated by soreness and tenderness at the epigastrium and under the lower end of the sternum, and by nausea and vomiting, sometimes with thirst. It was often very early observed; and when it and the preceding affection were present in the same case,—which was not infrequent,—it was difficult to determine which had been the first to appear, or whether they were coetaneous in origin. Indeed, they seemed often to have been prominent local manifestations of the constitutional disease, arising nearly at the same time. Although rendering the disease more or less severe, increasing the debility and general depression, and prolonging convalescence, the gastric complication was never fatal, or even dangerous. It was sometimes associated with considerable derangement of the biliary functions and secretion, with slight costiveness, and in some cases with diarrhœa; the irritation in these latter having seemed to extend along the digestive mucous surface.

18. *c. Bronchitis* was one of the most frequent and severe complications observed in the last two epidemics, especially in that of 1837. But it was different from the acute sthenic bronchitis usually observed as a primary disease, or as occurring in previously healthy persons. It was attended in many cases with more marked vital depression, with a more copious expectoration of a greyish, viscid, ropy, and less frothy mucus, which often quickly passed into a thin muco-puriform matter, than in idiopathic bronchitis. In most of the cases, both lungs were more or less affected, and the disease seemed rapidly to extend along the larger bronchi to the smaller ramifications, until, in the dangerous or fatal cases, the air-cells themselves became implicated. At the commencement of the bronchial complication, the cough was hard, dry, and severe; but expectoration soon became abundant,—the wheezing from the accumulation of the morbid secretion in the bronchi being often remarkably loud. The cough and the quantity of the sputa were generally increased at night, the former being frequently so severe, and the attendant dyspnœa so urgent, as to prevent the patient from lying down. When both lungs were gravely affected, the patient was obliged to sit or be shored up by pillows. In some cases, the sputa were remarkably abundant, consisting of a very fluid muco-puriform matter, almost from the commencement. In most of the bronchial complications, the *dyspnœa* was considerable, and especially when expectoration was difficult and the sputa copious; still it was often great when the discharge from the respiratory passages was neither abundant nor difficult. The rapid extension of this asthenic form of bronchitis throughout the lungs was most remarkable in the delicate, the aged, the cachectic, and those subject to asthmatic or bronchial disorder. In some instances it quickly superinduced a nervous or asthenic form of pneumonia or pleuro-pneumonia, with which it

further became associated; and occasionally it seemed to have given rise to more or less emphysema of the lungs. The mucous, or the crepito-mucous, rhonchus was generally heard in most of these cases. The pulse was usually upwards of 100, often above 110, and irregular. The severer forms of this complication often terminated fatally, owing to the quantity of the morbid secretion filling the smaller bronchial ramifications, infiltrating the air-cells or even the areolæ of the connecting cellular tissue, and thus occasioning asphyxia.

19. *d.* The *pneumonia*, or pleuro-pneumonia, with which influenza was often associated, was generally of a nervous or an asthenic form. It was either an early complication, or was consequent upon the bronchitic affection. It was indicated by oppression, weight, and anxiety in the chest; by difficult or anxious, breathing; by a crepitous, or crepito-mucous, rhonchus in the vicinity of parts where neither the respiratory murmur nor any morbid sound was heard, and where more or less dulness existed on percussion. The sputa were muco-puriform, distinct, copious, and but rarely bloody or rusty. This complication was always severe, was often further associated with bronchitis, and, in these cases, the patient could not lie on either side, but required to be propped up in bed. The changes observed in the lungs after death were different from those usually consequent upon idiopathic pneumonia (§ 32, 33.).

20. *e. Tubercular phthisis* was generally aggravated by the influenza; and was not infrequently called into existence by it, where the predisposition already existed, or where the tubercles were in a latent or crude state. In some instances, the subsequent stages of consumption were accelerated by it; but few cases terminated fatally during the epidemic seizure, unless at a far advanced stage of the tubercular formations, and then evidence of extensive bronchial disease was generally furnished both during the attack, and upon examination after death. Yet I met with instances of persons in far advanced phthisis, who either experienced comparatively slight attacks of influenza, or had not their malady greatly aggravated, or its course materially accelerated, by the epidemic.— Much of this seemed owing to the treatment pursued in these cases.—The complication of influenza with phthisis was not, in my practice, more frequently attended by *hæmoptysis*, than it is in other circumstances; although hæmoptysis was frequent in phthisis, subsequent to, or developed by, the epidemic malady.

21. *f. Pleuritis* was not a frequent complication, unless connected with pneumonia; but when it occurred, its characters were much modified by the primary epidemic distemper. It generally appeared insidiously, the pains attending it having been often mistaken for the pains of the chest and vicinity usually attending the severe cases of the epidemic; and the latter having often masked the former. In some instances, effusion from the affected surface had proceeded far, before the existence of inflammation was suspected; the matter effused, instead of having consisted more or less of fibrinous or coagulable lymph, as in the sthenic forms of phlegmasia, having generally been fluid, turbid, sero-albuminous, or sero-puriform, and abundant. Hence adhesions of the opposite surfaces were never produced by the pleuritis complicating influenza, although old adhesions were frequently found upon dissection of fatal cases. In rare instances, not only pleuritis, but also pericarditis of a similar character, co-existed with influenza.

22. *g. Rheumatic affections* were seldom observed, even in those subject to them, during the epidemic malady; but they more frequently occurred subsequently, as sequelæ. The wandering, and sometimes severe, pains, characterising influenza, could not be viewed in the light of a rheumatic complication. When rheumatism appeared, it was generally obstinate, and, unless very appropriately and energetically treated, aggravated and prolonged the disease, and protracted convalescence.

23. *h. The complication with disease of the heart or pericardium* was observed chiefly in persons who were previously the subjects of such disease. A form, however, of asthenic pericarditis was met with in rare instances, either alone, or in conjunction with pleuro-pneumonia or pleuritis. But, in such cases, the inflammation gave rise to a similar effusion to that observed in the associated pleuritis already noticed (§ 21.).

24. *i.* In some cases, influenza assumed so severe a character, as nearly to approach *low nervous* or *adynamic fever*, owing to the great depression of organic nervous power, and the delirium and other cerebral symptoms attending it. Yet the disease was very different from these states of fever; and chiefly as regarded the catarrhal or bronchial symptoms, the sharpness or acuteness of the attack at the commencement, the free and general perspirations early in its course, the less loaded and more moist states of the tongue, the pale and turbid condition of the urine, the less complete loss of muscular power, and the much shorter duration of the febrile phenomena, when appropriately treated, in the former malady.

25. *k.* Some other complications were observed, particularly *laryngeal*, *croupy*, or *tracheal irritation*, of various grades of severity, but generally of a similar character to the bronchial affection already noticed (§ 18.), with which these were usually associated. They were seldom, however, met with, as the only, or even as the most prominent, complication. In slight forms, causing, at first, more or less hoarseness, and a harsh, clanging, and dry cough, and, subsequently, a convulsive or strangulating cough, with difficult expectoration and viscid sputa, these affections were very common; and were often either a part, or the commencement, of the phlegmasia which extended from the throat to the bronchial ramifications,—the larynx and trachea presenting, in fatal cases, similar appearances to those seen in the bronchi and pharynx.

26. These were the chief local affections which complicated the last two epidemic catarrhal fevers, and rendered them severe and often fatal. Some of them, it will be seen, were antecedent disorders, not only rendering more violent the epidemic attack, but themselves becoming, in turn, more developed and aggravated by the constitutional disease. Others, again, were evidently called into existence by the epidemic malady, owing to latent predisposition, or to various concurring or accessory causes. Very generally, however, influenza did not supervene upon acute visceral or febrile disease, until the latter was subdued, or

the patient was convalescent. Thus, I saw several patients with bronchitis, pneumonia, &c., near the end of December, 1836, just before influenza had appeared; and, although the epidemic prevailed in the same family during the acme and subsidence of these diseases, it did not attack these persons, until convalescence had either commenced, or had made considerable progress. It was generally severe in such cases,—the constitutional and local affections presenting an asthenic character; but recovery took place in all.

27. *C. Exacerbations* or *relapses* of the disease were sometimes observed after premature exposures and errors of diet; but the relapses were not always more severe than the primary affection; and so rarely occurred, if once the patient was truly convalescent, that they were rather exacerbations, or prolongations, of the disease, in consequence of a superinduced complication, or the production of renewed bronchial irritation. Many of the affections, which were viewed as relapses, were cases of bronchitis or of tracheal irritation, caused by cold during convalescence, and increased or modified by existing disorder of the digestive canal and of the biliary organs, and by debility.

28. *D. Certain of the symptoms* require a brief notice.—The *tongue* was not materially affected in many: in some, it was white; in others, it was covered by a soft, or creamlike, or yellowish, mucus or fur. The *fauces, pharynx,* and tonsils were generally red. There was always loss of *appetite,* and generally *nausea* or *vomiting* at the commencement; in some, bile was thrown up. *Thirst* was not complained of in the majority of cases. The *urine* was usually thick or turbid, somewhat red, and deposited a pink sediment as the attack subsided. *Cough* was always present from the first day, and was often very severe for two or three days; but it was often prolonged, sometimes after the subsidence of the attack, and assumed a convulsive form. There was often *dyspnœa,* with more or less wheezing and restlessness; but chiefly in the complicated cases, or in asthmatic persons. The *expectoration* was chiefly mucous, and as already described, unless in the bronchitic or pulmonic complications, or in those subject to chronic catarrh or bronchitis; and in these it was muco-puriform. No morbid *rhonchus* or *râle* was heard in most of the simple cases, although the cough and dyspnœa were severe. The *pulse* was more or less accelerated, generally soft, weak, and occasionally small, especially as the disease advanced; but it was often irregular—being at one time sharp, hard, or wiry, for a short period, and then becoming soft and weak. The sharpness or fullness of the pulse sometimes led to bloodletting, which was seldom of service, even when the disease was associated with inflammation, unless prescribed in great moderation, and at a very early stage. In London, however, bloodletting was rarely indicated by the symptoms; the phlegmasia often complicating the disease, being decidedly asthenic, and more frequently aggravated than ameliorated by vascular depletions. The *blood* was sometimes buffed in the complicated cases; the buff being deep and gelatinous, but seldom cupped or tenacious. Much mental and physical depression *existed;* and the character of the *febrile* or *constitutional affection* was decidedly *nervous* from the commencement, vascular action being more or less asthenic or adynamic throughout. But the febrile symptoms varied much, not only at different periods, but also at the same stage, according to the constitution, previous health, and age of the patient, and to the severity and complication of the disease.

29. *E. The sequelæ of influenza* were sometimes more dangerous than the primary malady; and the severity or danger of these had frequently no relation to the violence of the epidemic seizure; for the consequent affections were often most serious in persons who had experienced a comparatively mild attack of influenza, and as frequently slight in those who were severely attacked. —*a. Tubercular consumption* was observed chiefly in those who had an hereditary tendency to the disease, and in whom tubercles had evidently existed in a latent, undeveloped, or crude state—the influenza having promoted their evolution.—*b. Chronic bronchitis* also not infrequently occurred; either the bronchial complication having degenerated into a chronic and asthenic form, or this form having appeared during convalescence from the influenza, owing to the predisposition left by it. In either case, the disease was obstinate, and required a restorative treatment and regimen, with change of air.—*c. Asthmatic affections,* often presenting a nervous, convulsive, or spasmodic character, in conjunction with bronchial congestion or irritation, and sometimes with considerable bronchial discharge, were occasionally met with in persons advanced in life. In these, the cough, dyspnœa, and wheezing were more or less distressing; and complete or even partial relief was afforded with difficulty.—*d. Disease of the heart* was sometimes a sequela of influenza; but it might have existed previously, although it did not become so fully developed as to attract attention, until subsequently to the epidemic attack. Indeed, a more or less asthenic *endocarditis* or *pericarditis* may have occurred as a complication of influenza at some period of its course—this latter rendering the former still more obscure, until the more advanced consequences of the complication, and the subsidence of the primary malady, rendered the nature of the lesions more manifest. However induced, there can be no doubt that lesions of the heart of various kinds, and such as usually result from inflammatory irritation, were often met with in those who had experienced severe seizures of the epidemic. In some, the disease of the heart was associated with asthma or with more constant dyspnœa, and seemed aggravated by the debility consequent upon the influenza, especially in chronic cases, and where the heart-affection was not decidedly inflammatory.—*d. Hæmorrhage* from the respiratory organs was occasionally met with in those labouring under phthisis; but it may also have arisen from congestion of the lungs and interrupted circulation through the heart.—*e. Dropsies,* especially of the *thoracic cavities,* were sometimes observed as consequences, more or less remote, of severe attacks of influenza, particularly where the lungs had been implicated, or where disease of the heart existed previously, or where asthenic pericarditis had existed as a complication. But still dropsy was not so frequent a sequela of this as of some other epidemics.—*f. Obstinate dyspepsia,* and other *functional disorders* of the *digestive organs,* were very common sequelæ of this malady; and generally required change of

air, with strict attention to diet, for their permanent removal. — *g. Rheumatism* was a not infrequent consequence of the epidemic, and, as far as my experience enabled me to judge, was most benefited by a restorative and tonic treatment, with antacids, sometimes with colchicum, and change to a dry pure air.

30. III. PROGRESS AND DURATION. — The disease generally presented an acute stage, lasting from three to five days, and, in the slighter cases, terminating either then, or in two or three days. But it more frequently, especially in the severer seizures, continued, in a less acute form, for a period varying from five to fifteen days longer. — The course and duration of the complicated cases were very indefinite; and the recovery from these, as well as from all the most severe attacks, was attended with great debility, which often continued for a long time, even although none of the *sequelæ* or consequences just mentioned were manifested.

31. IV. DIAGNOSIS. — *Influenza* may readily be confounded with *acute bronchitis*, and with common or *sporadic catarrhal fever*, but may easily be distinguished from them, by attention to the following circumstances: — Influenza commences with very manifest disorder of the organic nervous system, as in all other idiopathic fevers, or epidemic maladies; and, although a predominant affection of the respiratory passages soon takes place, yet the digestive organs and circulating system are also more or less deranged. The dyspnœa attending influenza is much greater, relatively to the other indications of disorder in the lungs, particularly those furnished by the aid of the stethoscope, than in the complaints just mentioned. The pains complained of in the head, loins, limbs, and about the insertion and edges of the diaphragm; the severity of the cough in the night, and the general insomnia; the physical depression, and the weakness and irregularity of the pulse; the epidemic prevalence of the disease; and the different effects of medicine in it, and in those disorders; further serve to distinguish between them. — Influenza differs also from the *catarrhal fevers* of spring and autumn, in the great debility, in the spasmodic pains and disturbance of sensation generally, in the nausea and vomiting, in the disposition to sweating, and the occasional appearance of an exantheme, and in the peculiar expression of the face, which attend it; in its almost universal prevalence, and in the danger to the aged.

32. V. APPEARANCES IN FATAL CASES. — The changes observed after death were referrible — 1st, to pre-existent disease; and, 2d, to the effects of the epidemic and of its complications: to these latter only attention need be directed. The *trachea* and *bronchi* contained more or less of a frothy, muco-puriform, and frequently sanguinolent, matter, which was most abundant in the smaller bronchi. The *mucous membrane* lining these parts was generally of a dull red, or of a livid or dark hue, from congestion of the small vessels, and softened and thickened. These appearances were sometimes confined to one lung, but they more generally extended to both. The *substance of the lungs* was often darker than natural, and of a livid or violet colour. The air-cells, and frequently the tissue of the organ, seemed partially infiltrated by a muco-puriform, or muco-sanguinolent, fluid, which rendered it denser, and less crepitant on pressure, than usual; and its vital cohesion was much weakened. In aged, asthmatic persons, the lungs were generally very dark-coloured, much softened, infiltrated with fluid, partially emphysematous, and otherwise changed; a dirty or turbid serum being sometimes effused into the cavities of the thorax. The *pleura* was occasionally partly or very extensively adherent; but the adhesions were always the consequences of old disease. The *blood* in the heart and large vessels was generally dark and fluid.

33. In the younger and more robust subjects, where the indications of associated pneumonia were the most manifest, the lungs were also of a dark hue, congested, infiltrated with a dark or sanguinolent fluid, much denser than natural, or splenified, no longer crepitant, but not truly hepatised, as in true or sthenic inflammation; for the matter thus filling the areolar tissue of the organ was not a coagulated or fibrinous lymph, but an uncoagulable fluid, which could be more or less completely squeezed out of the part. The substance of the lungs was also torn with greater ease than usual, and the bronchial mucous membrane and bronchi presented the appearances already described (§ 32.). Both lungs were thus diseased, in many cases; and, even when one lung only was affected, the inflammation was more or less diffused, as in other instances of asthenic phlegmasia. In some, the most depending portions of the lungs were most infiltrated and congested — showing that the changes had partly taken place at the time of, or subsequent to, dissolution. — Appearances of asthenic inflammation were, in a few cases, observed in the *heart* and *pericardium*, with the effusion of a dirty serum into the latter; and, as Dr. CLENDINNING has remarked, in his excellent paper on the disease, these lesions were generally associated with those produced by pneumonia and pleuritis. Old disease of the heart was met with in many aged persons; and, in those who had been labouring under tubercular consumption, the bronchial mucous membrane, and tissue of the lungs between the tubercular formations, presented very similar changes to those described. The *digestive mucous surface*, particularly of the pharynx, œsophagus, and stomach, was congested, and sometimes presented patches or streaks of a dark red, or livid hue. — I never saw the exudation of lymph or coagulable albumen in the small bronchi, resembling the false membrane of croup, which Dr. GLUGE says he met with, nor is it mentioned by any other writer. My own dissections were few; but I have adduced also the results obtained by Drs. CLENDINNING, MACLEOD, GRAVES, and others.

34. VI. CAUSES. — The seasons, and the state of the weather both antecedently and at the time of the outbreak of influenza, have had no share in its production. Whether appearing in spring, summer, autumn, or winter; or occurring in mild and dry, or in cold and moist weather; or prevailing in cold, temperate, or warm countries; it has presented the same general features: and, even in seasons and climates most likely to have rendered it more than commonly mild, it has sometimes assumed a severe form; whilst it has presented a milder character in countries where it might have been expected to have been a more formidable disease. No dependence, therefore, can be placed upon climate, season, and weather,

in modifying its severity or complications, although they doubtless have had more or less influence in this respect on some occasions.

35. This epidemic has not arisen from the prevalence of easterly, northerly, or other winds; for, not only have winds from such quarters prevailed without influenza having occurred, but it has broken out in different places during the prevalence of winds from different quarters. That it has not proceeded from cold in any form or way, is proved by the circumstance of persons who took the greatest care of themselves, as respects clothing and exposure, having been attacked as well as those who were constantly subjected to the vicissitudes of season and weather. Yet, in some instances, as Dr. GRAVES has remarked, exposure to cold determined the immediate access of the disease, or increased its violence when present; and I would add, gave rise to several of its complications. No kind of occupation seemed to protect from its visitation; nor did the impregnation of the air with gaseous fluids, usually considered disinfectant, have this effect. It is probable, from the very rapid progress of the complaint over nearly the whole globe, that it depended, either, as Dr. GRAVES suggests, "upon telluric influence — upon some agency connected with variations in the physical conditions which operate on the external surface of our planet;" or upon a very general change in the usual conditions of the electricity circulating on the surface of the earth: but these, in the present state of our knowledge, are merely conjectures.

36. As to the influence of *infection*, in causing and propagating influenza, some diversity of opinion exists: but the question admits of a tolerably easy solution. That the disease neither originated in, nor was diffused by, *contagion*, direct or mediate, seems satisfactorily proved, by the nature of the disorder, and by the phenomena and circumstances connected with its appearance and spread. No facts have been adduced of a contagious property, according to the meaning I have attached to the term (see art. INFECTION, § 1—3.), having belonged to it; whilst numerous circumstances, showing that it was devoid of such property, have been observed by all who were practically acquainted with it. The almost simultaneous outbreak of the epidemic in distant countries; the rapidity with which it traversed immense spaces; the fact of its often pursuing, in its spread, a different course from that of human intercourse; the great numbers attacked at the same time, when it appeared in a town or district; and the frequent suddenness of the seizure; showed that it proceeded chiefly from a very generally diffused change in the atmosphere, that modified or infected the system in a determinate manner. That this malady depended principally upon atmospheric influence, these and other considerations fully prove; but that, in some instances, other agents or causes concurred with, or aided this, the principal cause, may be admitted. These other concurring or aiding causes seem to have been the ordinary exciting causes of catarrh, and infection proceeding directly from those labouring under the malady. It was often observed that communincation with those already attacked appeared to favour the developement of the complaint in the healthy; for, when an individual came with the disease from a distance, the inhabitants of the house in which he arrived were usually the first attacked. But it must be conceded, that this infection was a very subordinate cause to that, upon which the epidemic principally depended; and that it was merely a concurrent and contingent circumstance in the diffusion of the complaint.

37. The disease was not very materially influenced in its spread by *age*. It was, however, most prevalent in persons of from 16 to 60; and, upon the whole, the least prevalent and most mild in children, although severe and complicated seizures were not uncommon even in them. It was very frequent, most complicated, and severe in the aged—from 60 upwards. *Sex* and *temperament* did not appear to have influenced the liability to an attack. It did not appear that a former seizure caused exemption from it afterwards. The Author attended several persons in the epidemic of January, 1837, who had been attacked, as well as others who had not been attacked, by that of 1833; but he also saw some who had the influenza of 1833, and who escaped that of 1837. He is acquainted with very few instances of entire exemption from both these epidemics. He and his family escaped on both occasions. Generally, when one in a family was seized, the majority of its members were soon afterwards affected; but often two or three were attacked so nearly at the same time that it was difficult to assign the priority to any one. The epidemic continued about six or seven weeks in a place; but a few cases occurred just before, and others not until a short time after, its general prevalence. A circumstance of some importance, although very frequently overlooked, in respect not only of the two latest, but also of former epidemics of this kind, has been observed, and recorded by several writers; namely, the appearance of the complaint, also as an epidemic, among many of the lower animals, particularly horses and dogs, for some weeks or months before the outbreak of it in the human species.

38. VII. NATURE.—It was evident, from an attentive consideration of its phenomena, that influenza partook largely of the characters of an epidemic fever. It was also manifest that the exciting cause of the complaint, whatever may have been the nature of that cause, existed in the air, and that, by this medium, it morbidly impressed the organic nervous influence, especially in the respiratory organs, where its first invasion took place in the process of respiration; these organs thus becoming and continuing prominently disordered. This primary and especial affection of the organic nervous influence was shown by all the premonitory and early symptoms. That this affection was not only peculiar or specific, but was further characterised by depression — that the organic nervous energy was remarkably weakened as well as otherwise changed—was evinced by the lassitude and debility which were present from the commencement of the seizure; by the affection of the digestive and circulating organs; by the spasmodic and nervous pains in the trunk and limbs; by the states of vascular action and of the blood; and by the general debility produced by the complaint. The circumstances of the pains not having been aggravated by pressure, of their wandering and diffused character, and of the spasmodic nature of the cough, were proofs that the disease was not essentially inflammatory, although

inflammation of a more or less asthenic form sometimes supervened. This position was further strengthened by the state of the circulating organs and fluids, and by the appearances observed in fatal cases. That fever, or rather increased temperature of the surface of the body, was not remarked in some cases, and in some even of the most dangerous complications of the disease, did not militate against the opinion of influenza being an epidemic fever *sui generis*, with early and prominent disorder of the respiratory passages and organs.

39. VIII. TREATMENT.—The *milder* and *simpler states* of influenza required little more than the early restoration of the cutaneous exhalation by diaphoretics, and the evacuation of disordered secretions by mild chologogue purgatives. In the majority of cases, five grains of blue pill and six of compound extract of colocynth, with one of ipecacuanha, given at bed-time, and a mild aperient the following morning if these did not act freely, were extremely useful; but, if there were nausea or retchings, seemingly proceeding from biliary disorder, a mild *emetic*, or the warm infusion of chamomile flowers, was premised with advantage. Subsequently diaphoretics, consisting of camphor mixture, solution of the acetate of ammonia, and the spirit of nitric æther, sometimes with a little ipecacuanha or antimonial wine, were given every third or fourth hour. In many instances nothing further was necessary; but, when the bowels required aid, a draught consisting chiefly of the compound infusions of gentian and senna, or a pill containing compound extract of colocynth, the extract of hyoscyamus and ipecacuanha, was taken at bed-time.

40. In the *more severe attacks*, and when much febrile excitement and heat or dryness of skin were present at the commencement, a full dose of calomel, with James's powder, and a grain of camphor, was given at bedtime, a purgative draught being taken in the morning. The diaphoretic prescribed above (§ 39.) was also taken every three hours, with a few drops of antimonial wine, until a free perspiration was produced. A warm bath was occasionally prescribed at bed-time, and generally was of great service. After a free perspiration had been procured, a few drops of the aromatic spirits of ammonia were substituted for the antimonial wine; and, as the disease declined, mild restoratives or tonics, and a light diet, were found most beneficial.

41. When the *cough* was very severe, and dry, or attended by much soreness at the chest, a larger dose of calomel and James's powder was prescribed, as much tartarized antimony as the stomach could bear was given in the diaphoretic mixture (§ 39.), and the warm bath, and warm demulcents, were resorted to. As soon, however, as the cough became more loose, and the defluxion from the respiratory surfaces either free or abundant, the calomel and the antimonials were relinquished, and the less depressing diaphoretics prescribed. The application of a mustard poultice, or of the warm turpentine fomentation, to the chest, or of a rubefacient plaster between the shoulders, was also serviceable. At an advanced stage of these cases, the following pills, either alone or in addition to warm diaphoretics, were found most beneficial, especially in aged or weak persons.

No. 268. ℞ Camphoræ rasæ, Massæ Pilul. Ipecacuanhæ Comp., āā ℈j.; Extr. Hyoscyami (vel Extr. Papaveris) ʒss.; Mucilag. Acaciæ q. s. M. Fiant Pilulæ xviij., quarum capiat duas, quartâ, quintâ, vel sextâ quâque horâ.

No. 269. ℞ Massæ Pilulæ Scillæ Comp., Massæ Pilulæ Galbani Comp., āā ℈j.; Pulv. Ipecacuanhæ gr. vj.; Extr. Conii (vel Extr. Papaveris) ℈ij.; Olei Anisi q. s. M. Fiant Pilulæ xxiv., quarum capiat duas, quartis vel sextis horis.

42. When influenza was *complicated with bronchitis*, or with *pneumonia*, a modification of the above treatment was generally requisite. Much mischief, however, was produced—as I witnessed in several instances, in consultation—by having recourse to a too antiphlogistic means, and to large depletions, in these complications. Not infrequently, also, congestion only of the bronchial mucous surface, or of the lungs, and great accumulations, or inordinate secretions, of mucus in the smaller bronchi, were mistaken for bronchitis and pneumonia, and treated accordingly. Even where inflammatory action was more decidedly evinced, the fact of its association with an asthenic or adynamic condition of nervous power and of vascular action, was often overlooked, and a truly *nervous* or *asthenic pneumonia*, or *bronchitis*, was treated too generally in the same manner as the primary and uncomplicated states of these inflammations. The same remarks are nearly equally applicable to the occurrence of *pleuritis*, or of *pericarditis*, in the course of the malady. Even for these, bloodletting and the rest of the antiphlogistic treatment required the utmost caution. They were beneficial only when *very early* and moderately prescribed. I derived great advantage in these complications, from the application and repetition of embrocations or fomentations with spirits of turpentine, or with either of the *liniments* in the APPENDIX (F. 296. 311.), until considerable redness, or even vesication, was produced. Calomel or blue pill, with camphor and henbane, and sometimes with digitalis or ipecacuanha, or James's powder, was generally of service; and a diaphoretic mixture of camphor julep, the solution of the acetate of ammonia, spirits of nitric æther, or a small dose of antimonial or ipecacuanha wine, was very commonly prescribed. As the more inflammatory state subsided or disappeared, the aromatic spirit of ammonia was substituted for the antimonial preparation; and a restorative regimen and change of air recommended. (See arts. LUNGS—*Asthenic Inflammation of*; and PLEURA—*Asthenic Inflammation of*.)

43. If *bronchitis* degenerated into a chronic state, camphor, the decoction of senega, or preparations of squills or of ammoniacum, were employed; and the more permanent derivatives and counter-irritants resorted to. In such cases, the means described in the article BRONCHI (*Chronic Bronchitis*, § 93—103.), rarely failed of removing all disorder.

44. In the complications with *affection of the throat, larynx, or trachea*, the warm terebinthinate fomentations or embrocations, already noticed, applied around the throat and neck, never failed of imparting complete relief; the rest of the treatment already described being generally adopted. Blisters to the throat were injurious; but, when applied to the nape of the neck, or over the sternum, they were often of service. Early in these complications, as well as in the association with bronchitis, an emetic of ipecacuanha was frequently beneficial. The warm bath, the semi-

cupium, and pediluvia were also sometimes of service. When there was much tenderness of the epigastrium, and *gastric irritation*, a mustard poultice, or the warm terrebinthinate fomentation, or other rubefacients, applied to this region, and purgative enemata, generally afforded relief.

45. At an advanced stage of the complaint, when, in consequence of its severity or complications, the powers of life indicated much depression, by the state of the pulse, the perspirations, or the abundance of the sputa, or difficulty of expectoration, camphor, quinine, ammoniacum, senega, ammonia, and other expectorants and restoratives, in liberal doses, were indispensable.

46. During convalescence, change of air, a restorative regimen, and the use of flannel nearest the skin, were commonly necessary. In other respects, the same means as have been advised for the treatment of Debility (§ 35. *et seq.*), and for convalescence from Fever (§ 167. 612.) were then requisite.

INSANITY. — Syn. *Μανια, παραφροσυνη, παραφρονια, παραφρονησις*, Hippocrates, Galen. *Paraphrosyne, Paraphobia, Dæmonia, Dementia, Moria*, Auct. Lat. *Mania*, Boerhaave. *Amentia*, Vogel, Sagar. *Delirium Maniacum*, Hoffmann. *Phrenitis Apyreta*, Sauvages. *Vesania*, Linnæus, Cullen, Parr. *Ecphronia*, Good. *Mania Universalis*, Young. *Unsinnigheit, Tollheit, Schwermuth, Mondsucht*, Germ. *Folie, Démence, Phrénèsie, Manie*, Fr. *Mania, Insania*, Ital. *Madness, Mental derangement, Lunacy, Mental aberration, Unsoundness of Mind.*

Classif. — 2. *Class*, Nervous Diseases; 4. *Order*, Mental Disorders (*Cullen*). 4. *Class*, Diseases of the Nervous Function; 1. *Order*, Affecting the Intellect (*Good*). I. Class, III. Order (*Author*, in *Preface*).

1. Defin. *A deviation from, or perversion of, the natural and healthy state of the mind, as manifested either by the moral emotions and conduct, or by a partial or general disorder of the intellectual powers and understanding.*

2. *Insanity* — *Insanitas* — was formerly employed to signify a deranged state of the health, either of body or mind. But it became more especially applied to mental disorders — *Insania* — and lately has been entirely limited to them. It may be considered to comprise all morbid manifestations of mind, whether partial or general; or with whatever series of symptoms they may be accompanied, whether with those of excitement, or of depression, of any of the functions, either of mind or of body. Insanity, however, and especially certain moral states of it, is often nothing more than an exhibition of the natural character, and moral disposition of the individual, over which reason has ceased to exercise its control, or which has become remarkably prominent, or even per-

verted by excessive indulgence and unexercised restraint. The inordinate gratification of passions or moral emotions, not only gradually weakens the influence of reason and of self-control, but also imparts to these emotions a perverted and truly morbid character, and allows them to assume forms at variance with the established opinions and habits of the world, and with the laws of society.

3. It is extremely difficult, if not impossible, accurately to *define* insanity, or to draw a line of demarcation between it and what has usually been denominated singularity of opinion, or eccentricity of conduct. The latter states, viewed either in their moral or in their intellectual relations, insensibly pass into various acknowledged varieties of the former, and are often merely states of transition from the healthy mental manifestations, to a condition indisputably morbid. Since the time of LOCKE, it has generally been considered, that the insane have not lost the power of reasoning; but, having entertained, as real, some illusion or erroneous impression, they err, by reasoning from wrong premises. This idea appears to have been adopted by CULLEN, who remarks, that "there is generally some false perception of external objects, and that such false perception necessarily occasions a delirium or *erroneous judgment*, which is to be considered as *the disease*." But this, too limited a definition, was more extended where he states insanity to be, "in a person awake, a false or mistaken judgment of those relations of things which, as occurring most frequently in life, are those about which the generality of men form the same judgment, and particularly where the judgment is very different from what the person himself had before usually formed." But, as Dr. PRICHARD has remarked, these definitions apply only to one class of cases, and especially to *melancholia*, *monomania*, or *partial insanity* — to these forms, in which certain illusions exist, and the judgment is *comparatively* clear on all other topics unconnected with the illusions entertained. But, although the judgment seems comparatively clear on other topics than those connected with the morbid illusion, yet it must not be considered with LOCKE, that the insane make right deductions from their illusions. As Dr. CONOLLY has more justly observed, "the judgment is but the result of comparison; comparison is alternate attention; attention is a faculty dependent on the brain," — and one, I would add, which is most early and most generally disordered in mental diseases. I therefore quite agree with this writer, that, in all cases, even of partial insanity, the judgment is more or less weakened and perverted.

4. Besides the above limited forms of insanity, there are others of a more general and manifest kind — namely, 1st, *Maniacal* or *raving insanity*, in which the mental manifestations are more generally and more severely affected, the derangement being characterised by great excitement, wildness, violence, and absurdity; 2dly, *Imbecility*, and *Incoherent*, or *fatuous insanity*, in which the mind is altogether incapable of any effort; the intellects being remarkably impaired, and the ideas being rapid, unconnected, or incoherent. To the preceding forms, in which the *intellectual manifestations* are primarily and chiefly disordered, some recent writers have added another, viz. *Moral insanity;* in which the intellectual powers are but little, or not very manifestly, impaired; the disorder appearing chiefly in the emotions, habits, and conduct. In this form of mental disease, the moral and active powers are perverted or depraved; self-government is either greatly impaired, or altogether lost, and the individual is incapable of conducting himself with propriety, in many of the relations of business and society. As Dr. PRICHARD observes, "his wishes and inclinations, his attachments, his likings and dislikings, have all undergone a morbid change; and this change appears to be the originating cause, or to lie at the foundation of any disturbance which the understanding itself may seem to have sustained, and even, in some instances, to form, throughout, the sole manifestation of the disease." It must not, however, be supposed, that the understanding, in such cases, is altogether unaffected. It may not present any very obvious delusion or aberration from the usual condition; but it is certainly more or less weakened; and the patient is incapable, from habit or from impaired nervous power, of exerting those manifestations of mind upon which judgment and self-control depend, with the vigour and precision of health. Besides, the indulgence, or the inordinate excitement or sway, of the emotions and passions, leading to moral insanity, necessarily tends to weaken or to obscure the understanding, and ultimately to overturn it altogether.

5. Whilst we observe insanity arising almost insensibly from the misdirection of certain manifestations of mind, from the excitement or the over-indulgence of others of these manifestations, and from the utter neglect of some of them, aided by an impaired power of attention and comparison; we not infrequently also perceive it to proceed from those diseases and injuries which affect, more or less remarkably, the functions, circulation, and organisation of the body, and particularly of the brain and nervous systems: — fevers, in which vascular excitement becomes inordinate, or in which organic nervous or cerebral power is much depressed, frequently, derange the mental powers in their course; and the derangement, owing to organic lesion produced in their progress, may become more or less permanent. The cerebral functions are generally disordered in the more severe cases of inflammation of the brain or of its membranes, and the disorder often assumes a most violent form; but it either entirely disappears, or partially subsides, with the removal of the organic condition upon which it depended, unless when the brain has sustained some injury that unfits it for the performance of its offices. In all these instances, however, the mental alienation is merely a consequence, or symptom, of the bodily disease, which has assumed its specific form and character before the mental affection appeared. It must not, from this, be supposed, that mental disorder is not, in its more chronic and primary forms, quite unattended by signs or symptoms of physical disease, referrible either to the system generally, or to the brain more particularly, or even to both. Cases of insanity are comparatively few, in which no indication of such disease is to be traced; the chief differences being, the obvious nature, the extent, the duration, and the kind of bodily affection which has preceded, and which accompanies the mental disorder.

6. When, however, insanity has proceeded

from bodily disease, or from external injury, the latter either may have been entirely removed, or its effects only may remain; the former enduring either for a time, or more permanently, owing to the consequences of the physical affection upon the nervous power, or upon the intimate organisation of the brain, and yet the organic functions may manifest little or no disorder.

7. *Insanity* may, therefore, be viewed as a generic term, comprehending every grade of *perversion* of the *moral*, or of the *intellectual*, or of the *instinctive, manifestations of mind*, or, of any two, or of all these classes of manifestations, from the healthy states,— to such perversion, a more or less manifest but variable alteration of the *sensations, perceptions, judgment*, and *voluntary movements*, being usually added; or, in other terms, the essential phenomena of insanity are — a more or less manifest or extensive change of the functions of the brain from their accustomed healthy condition — of the sensibility, the perceptions, the intellectual and moral powers, the judgment, and the movements, without any profound, obvious, or durable affection of the organic functions.

8. Yet these latter functions are not always, or even generally, devoid of disorder. They have been too commonly either overlooked altogether, or imperfectly attended to, or insufficiently investigated; the predominance of disorder of the cerebro-spinal nervous system, and preconceived notions of the relations of mind to organisation, and of the nature of insanity, entirely occupying the attention of the observer.

9. The history of medical literature, in respect of insanity, shows, that the study of the malady, and a knowledge of its pathology and treatment, have been long influenced and retarded by prejudice and superstition, by attributing all mental disorders to supernatural agency, or by considering them in the spirit of system. It has been justly remarked by M. Foville, that works on mental alienation present the two principal characters distinguishing medical writings; — the one class being dictated by observation, and containing information, the accuracy and the utility of which can never be impaired; the other imbued with the spirit of system, and manifesting all the follies that may be conceived. The chief advantage that can be derived from the latter class of writings is, to induce us to examine, for the guidance of our own opinions, the phenomena of mental disorder with the strictest attention; to limit ourselves chiefly to the description of what we observe, and to submit with the utmost caution to the ambition of explaining.

10. In *treating of insanity*, I shall closely adhere to the results of observation, and describe— 1. The phenomena, the essential and accessory symptoms; 2. The diverse forms and classification; 3. The terminations; 4. The organic lesions observed in fatal cases; 5. The predisposing and exciting causes; 6. The physiological pathology; and, 7. The treatment of insanity. — *Connate Insanity* or *Idiotcy, Puerile Imbecility, Puerperal Insanity*, and, lastly, *Suicidal Insanity*, will be afterwards considered in distinct chapters.

11. I. Symptoms of Insanity. — The study of the phenomena of insanity, according to the several functions chiefly affected by it, is of great importance, not only in arranging the various forms of the malady, but also in classifying the patients, and in determining with precision and success the method of treatment. In the general view, therefore, which I am about to take of the essential and related symptoms of insanity, I shall consider,—1. Those furnished by the *sensibility*, or connected with the *impressions*, the *sensations*, and the *perceptions*; 2. The phenomena exhibited by the *instinctive*, the *intellectual*, and the *moral manifestations*; 3. The symptoms connected with the *locomotive apparatus*; and, 4. The phenomena furnished by the *organic functions*. In the *general description* here about to be entered upon, I shall confine myself to those states of insanity, the existence of which admits not of dispute, and leave, until I come to the consideration of the special forms of alienation, the discussion of those *states* which are the least manifest, or which have not been generally admitted as constituting forms of insanity, either from their *slight or partial nature*, or from the circumstance of the *moral manifestations* being chiefly affected, the intellectual powers being much less prominently disordered (§ 4.).

12. i. The Symptoms furnished by the Sensibility are extremely numerous and diversified. They consist chiefly of false perceptions, arising from one or other of the following sources: — 1st, from disorder of the organ receiving the impressions; 2dly, from an affection of the nerves conveying the impressions, the organ itself being sound, 3dly, from profound disease of the parts destined to perceive them, the morbid impression taking place without any external excitement or cause; and, 4thly, from disorder of the general sensibility. But, as will be shown in the sequel, false perceptions, or illusions, more frequently proceed from two or more of these sources, than from any one singly.

13. *A. False perceptions arising from a disorder of the organs receiving the impressions*, are evinced by the state of these organs, particularly in regard of the presence of actual disease of them, and by the effects following the abstraction of their respective stimuli. The existence of disease will generally be ascertained upon a close examination of the sense, whose functions seem especially disturbed; and it is not infrequently observed, both where disease of the sense exists, and where it cannot be detected, that the shutting out of the appropriate stimulus — as by closing the eyes, or the ears, or the nostrils — arrests the morbid perception haunting the patient, by preventing the production of sensation. Esquirol, Reil, and Foville suppose that, where the morbid perception thus ceases upon shutting a particular sense, the cause of it exists in that sense: but this is not the case; the error arising from the circumstance of their confounding, with most of their countrymen, sensation with perception. A sensation will be morbid where the organ is disordered, but it will not necessarily be followed by a morbid perception, unless either the nerves conveying the sensation, or the brain itself taking cognisance of the sensation, be disordered, as respects either the state of its organisation or circulation, or the discharge of its functions. In cases, therefore, where closing the organ of sense causes a morbid perception to cease, such perception is not to be referred altogether to the state of the senses, but partly also to the organ of intelligence — to the understanding, which is obviously incapable of correcting or judging aright the re-

port conveyed by the sense especially affected. Indeed, the intellect may be so weakened as to be more than usually susceptible of derangement, either when inordinately excited by the senses, or when manifest disease of them exists. In cases of this description, the mind is incapable of paying due attention to the various circumstances connected with the morbid sensation or impression, of comparing them, and of judging them as in health; and this obtains especially when the sensation is novel, or even indistinct, as well as when it is inordinate, or too strong, relatively to the nervous susceptibility — to the cerebral power of the patient; and when it either forcibly or unusually impresses a mind already more or less deranged. Although, therefore, the disorders referrible to the senses, as ophthalmia, amaurosis, ottitis, ozena, caries of the teeth, &c., are sometimes concerned in the production of false perceptions in the insane; yet equally much, if not more, is to be imputed to the brain itself, and to its functions, which are mainly concerned in producing the morbid perception, and are obviously incapable of ascertaining the illusion: the morbid *sensation* appertains to the sense, and the nerves connected with it, but the false *perception* is chiefly the act of the brain.

14. *B. False perceptions without disease of the organs of sense.*— False perceptions of this kind have been called *illusions* by some, and *hallucinations* by others. M. Esquirol proposes to confine the latter term to them; and he defines them to be sensations perceived at a time, when there are no appropriate external objects present to excite them in the organs of sense. This class of false perceptions is much more common than the foregoing, and occurs in every possible form. Both the blind and the deaf may be subjects of illusions of the senses of sight and hearing respectively. The majority of those who are haunted by hallucinations of this kind suffer more in solitude, in darkness, and during silence, when the senses are in a state of repose, than in other circumstances. The distractions, incitements, and sensations experienced in society sometimes allay or obscure these illusions; but, however powerful, much more frequently they have no such effect, the mind continuing, nevertheless, to be engaged only with its morbid perceptions. The patient, when he speaks, is interrupted by them; he answers to voices which call upon or address him, or contemplates objects which have no existence.

15. Sometimes the illusions relate to one sense, and occasionally to more than one, or even to all the senses. Those of hearing are the most common; next those of sight, smell, and taste; the illusions connected with the two last being often associated. Those belonging to the sense of touch are the most rare.

16. Darwin supposes that hallucinations proceed from inflammation of the origin of the nerves of sensation; and M. Esquirol says, that "the false sensations of those subject to hallucinations are images and ideas reproduced by the memory, associated by the imagination, and personified by habit. A person in such a state converts the product of the understanding into a corporeal form; he dreams while he is awake; but, in those who dream, the ideas which were entertained while awake continue during sleep, whilst he who is in a delirium perfects his dream when waking." M. Foville justly remarks upon this opinion of M. Esquirol,— 1st, That hallucinations often do not furnish precise or determinate sensations like those which memory recalls — confused objects, or vague sounds, &c. are frequently only seen or heard: 2d, With many, however diversified or rapid the succession of ideas engaging the imagination, the illusion continues limited to one sensation, and is always reproduced in the same form; the patient always sees the same object, hears the same voice, or inhales the same odour: 3d, The delirium of the insane depends, in many cases, upon false sensation. All the wanderings of the mind are only the consequences of this. When patients recover, they say, "I have seen and I have heard as distinctly as I now see and hear you," while at the same time they are able to give an account of the errors of their imagination: 4th, In some insane persons, the hallucinations have preceded the delirium, and have been recognised by the patients themselves at the commencement as false perceptions; but at a later period, when combined with intellectual derangement, they have been regarded by them as real: lastly, One sometimes finds, in cases of hallucination, changes of the nerve destined to convey impressions; and although it may not be readily conceived how an alteration of the optic nerve, for instance, determines false perceptions relative to vision, it cannot be more easily explained wherefore disease of a nerve of motion in neuralgia causes involuntary movements of the muscles; we may as well believe that alteration of the nerve is the true and sole cause of the hallucination, although in the healthy state the will may be the only cause of voluntary motion, as that external excitants, the impressions on the organs of sense, are, in health, and during waking hours, the only natural cause of all sensation and of all perception. There is, besides, this analogy between the two cases,—that neuralgia of a nerve of motion does not ordinarily bestow the influence of the will on that nerve, and by consequence upon the muscles, and that the alteration of a nerve of sensation giving rise to hallucinations does not destroy the perception of sensorial impressions, although it often disturbs and impedes them.

17. It is much better supported by close observation and *post mortem* research, and hence much more probable, that illusions or hallucinations arise from lesions of the nervous parts intermediate to the organs of sense and the centre of perception, or from alterations of the parts of the brain into which the nerves of sensation enter, or in which they terminate. Illusions similar to those which occur in the insane, sometimes take place in persons whose intellects are sound; but a healthy understanding appreciates the false perception correctly, whereas the disordered mind confounds them with realities. It may hence be inferred that they are the effects of lesions which do not necessarily or constantly implicate the understanding, but which more frequently, owing to intensity or extent, affect the intellectual faculties, and especially the powers of attention and reflection.

18. Whatever may be the point of organic departure of hallucinations, they are lively or sad, capable of inspiring sentiments of benevolence, or of arming the hand of the maniac with an instrument of homicide. The supporters of the doctrine

of **Gall** suppose that the characters they assume entirely depend upon the portion of the brain affected — upon the point in the organ whence they proceed. The effects, however, of hallucinations upon the minds of the insane are undoubtedly as real and as positive as the impressions produced by external excitements.

19. *C. Delusions or false perceptions connected with the general sensibility.*— These disorders, from the most simple and circumscribed to the most general and complicated, are constantly met with in mental diseases. Persons who believe that they have in the belly, or in the chest, or in the head, an animal which preys on them, are as much the subjects of disordered sensations as those who say that they are without a stomach, or a heart, or head, and who otherwise are tormented by the most strange feelings. Those who believe that they have the devil in their bodies are victims of morbid sensations, which their disordered mental faculties refer to this cause. In many cases the delusion, false perception, illusion, or whatever else this kind of symptom may be called, evidently results from a state of suffering — from disease in the parts to which the delusion is referred. They are, in fact, symptoms dependent upon local lesion, traces of which are generally discovered on examination after death, the morbid sensation being misinterpreted by the erring judgment of the patient. M. **Foville** justly remarks that, without the state of pain, or morbid sensation, occasioning the delusion, the delirium of the insane might take another direction, and might be more easily appeased; and that one of the most efficacious means of attaining this object is to remove, when this can be done, the pains or sensations which give rise to the delusion.

20. In some instances, the delusion is unattended by any appreciable disorder of the part to which it is referred. It may depend, judging from analogy, upon an alteration in the nerves conveying impressions made in parts which they supply, or to which they are distributed; or even in those which are connected, or sympathise, with a disordered structure. The well-known example of pain referred to parts removed by amputation may be adduced in support of this view. — From what has now been stated, the delusions depending upon the general sensibility may be divided into — 1st, Those which seem to proceed from some alteration or lesion of the parts to which they are referred; and, 2dly, Those which seem to depend rather upon the state of the nerves transmitting the sensations, or upon the nervous centres themselves, than upon any appreciable lesion of the parts which are the seat of the delusion.

21. *a. Delusions with lesion of the parts to which they are referred.*— Many instances of this kind of delusion have been mentioned by authors. M. **Esquirol** states, that in one of his patients there existed considerable tension of the abdominal muscles, with tenderness of the abdomen. The devil, the patient said, had placed a cord from the pubis to the sternum, and a demon in her body, which burned, pinched, and bit her heart, and tore her entrails. Amongst other alterations found after death, the usual changes consequent upon chronic inflammation of the peritoneum and pericardium were found. Here the relation between the symptoms of the physical change and the mental delusion is sufficiently manifest. The same writer, amongst other instances, mentions the case of a female who believed that she had no longer any body, and that it had been carried away by the devil, for she felt nothing. M. **Esquirol** inserted a pin under the skin of her arm, without causing any evidence of pain. The loss of sensibility was evidently in this case connected with the production of this particular delusion. Another female fancied that the devil lay with her: she had constant pain and tenderness in the region of the uterus; and these were doubtless connected with the origin of the insane idea. There is here a very evident similarity of these delusions to the false perceptions attending disease of an organ of sense. All these morbid sensations are correctly judged, and their real natures appreciated, by the sane mind; but the disordered intellect is unable thus to recognise them, variously transforms them, and contemplates the forms into which it changes them, as real existences; superstition, previous habits and occupations, predominant feelings and religion, severally imparting to them the shapes which they assume, or the colour and character which they present. Similar to the above instances is one mentioned by M. **Foville**. A man, who received a severe wound at the battle of Austerlitz, continued insane ever since. His delusion is founded on that which he no longer recognises; he has lost the sensibility of the surface; and he believes that he no longer exists. He says, that that which you see there is not he; that it is a machine which has been made to resemble him, and which is very badly made. This man often falls into a state of complete immobility and insensibility, which last several days. Vesicatories and sinapisms never produce the least signs of pain. He often refuses to eat, saying that the machine which has replaced him has no belly, and that it has no need of food. His external surface and extremities evince no sensibility. The strange delusion which this patient labours under is manifestly founded on the loss of sensibility in these parts, and on the absence or marked modifications of organic sensibility.

22. *b. Delusions connected with the general sensibility that are independent of alteration of the parts to which they are referred,* seem to be more rare than those in which some lesion or other exists. It is the reverse in regard of false perceptions connected with the special sensibility — with the organs of sense. Not infrequently, however, these different kinds of false perception — of delusion and hallucination — are associated in the same case. The delusions of most insane persons have more or less reference to, or are influenced by, their education, their habits, their prejudices, their studies, their fears, &c.; and are often attributed by them to sorcery, to demons, to various physical causes, &c. A weak superstitious person believed that he had the devil in his belly. For a long time he could not make out how he got there; but he at last fixed upon the idea, that his father sold him to the devil in the presence of a notary for a sum of money. Just before he was taken ill, this young man accompanied his father to a notary, where they met a stranger who paid the father some money. This was in hot weather, and, on leaving the notary's office, the young man took some glasses of bad cider, and

complained soon after of pains in the abdomen, which have since continued to afflict him; and it was upon this circumstance he based his delusion.

23. Too great importance cannot be attached, in the practice of mental disorders, to the various lesions of sensibility, or too much attention paid to false perceptions and delusions of all kinds, both as respects their connection with physical lesion, and as regards their consequences, or influence upon the subsequent course of the malady. It is very manifest that the patients, who are the most dangerous to themselves and to those who are about them, are those who are subject to some one of these false perceptions or delusions. One insane patient hears a voice, which says to him, kill him or them. He resists the impression for some time; but at last believes it to be a supreme command, and obeys it. Another has recourse to suicide, either to avoid the punishment or distress of these hallucinations, or in obedience to orders, which he believes he has received from the Almighty, and which he is bound to execute. There is much more reason to distrust a maniac, who is subject to delusions or hallucinations, and to exercise strict control over him, than one who is not so afflicted.

24. All the foregoing kinds of false perceptions require also very close observation, especially with reference to their physical relations, — to the states of the organs to which they are referred, — in order that appropriate methods of treatment should be employed. It is obvious that, if the delusion be founded upon, or in any way connected with, functional or structural lesion, means should be used to remove such lesions; for, as already shown (§ 19.), organic disorder either occasions, or perpetuates, or aggravates, the morbid sensation, which the deranged mind perceives or construes falsely.

25. *c. Various other lesions of sensibility are often observed.*—Insane persons often tear themselves with their teeth or nails, without manifesting the least pain. Some eat straw, grass, &c.; some even their own excrements; and others gnaw their fingers or extremities. Patients have, in a few instances, picked or scratched parts of their own bodies, until large cavities or holes have been thereby made (ESQUIROL, FOVILLE, &c.). Some possess a remarkable power of bearing, without suffering, extremes of heat and cold. Some authors allege this to be general among the insane, but this is an error: the greater number do not manifest any sensible difference in this respect from the healthy. Others deny this altogether; but it is certain that many insane persons bear, without appearing to suffer, and without feeling the least inconvenience, the most excessive cold. CURRIE, RUSH, ESQUIROL, FOVILLE, and others, cite numerous instances proving this circumstance, — not the least coryza, or catarrh, or complaint whatever, having followed the exposure to cold. Some patients can fix their eyes upon the most intense light, and even upon the sun, without being dazzled thereby. M. FOVILLE adduces several instances, where vision was by no means weakened by having the eyes fixed for some time upon this luminary, in the month of July; the patients being able to read, immediately afterwards, a book printed in very small characters. Most insane persons readily addict themselves to the use of tobacco. They smoke, chew, or snuff it with avidity — females as well as males — when they can obtain it.

26. ii. SYMPTOMS APPERTAINING TO THE MORAL, INTELLECTUAL, AND INSTINCTIVE MANIFESTATIONS OF MIND. — The disorders of these manifestations are as numerous as the possible combinations of our ideas, and as diversified as our passions, propensities, prejudices, affections, and education. They present themselves under two forms: in some cases they have reference only to a single train of ideas; in others, they comprise a greater number. It is especially to this class of symptoms that the French pathologists have applied the term *delirium* — the disorder of the mental faculties forming with them the delirium of the insane; and upon the limits or extent of this disorder has been founded the division of intellectual derangement, or of the delirium, into partial or exclusive, and vague or general. The mental disorder, moreover, may be evinced chiefly in the moral, or in the intellectual, or in the instinctive, manifestations, or it may extend itself much more generally. It is according to the nature and extent of the disorder, that arrangements of mental diseases have commonly been attempted. In the one class, whatever may be its limits or extent, there is only a perversion, or an aberration, of the faculties; in the other, the faculties are altogether lost or obliterated; and this privation is either congenital or primary, or accidental or acquired. " Who is there," says M. ESQUIROL, " who can flatter himself to have observed, and to be able to describe, all the symptoms of mania, even in a single individual?" It is particularly to the very extensive class of symptoms now under consideration, that this reflection is applicable. How are we, observes M. FOVILLE, to comprehend the fugitive and multiplied shades of general delirium? How are we to trace the infinite subtilties of partial delirium, or monomania? In *general delirium*, or *maniacal* and *incoherent insanity*, ideas the most extravagant, images the most fantastical, associations the most discordant, emotions the most opposed, succeed each other with electric rapidity. The maniac confounds in his mind heaven, earth, and hell, his domestic affairs, his affections, politics, and morals. He speaks in verse, sings, laughs, weeps; utters his sentences with marked or peculiar emphasis; he speaks by turns in all the languages he may know; retraces his steps, lifts or extends his hands or tosses them right and left; dances, jumps, and utters menacing cries; rushes on his companions, tears all that comes in his way; strips himself naked, rolls on the ground, &c. &c. In these cases the functions of mind are not destroyed, but they are morbidly excited — they are actively deranged — and are no more like their healthy condition, than convulsions resemble the quiet walk of a man in health. On the other hand, in *partial insanity*, or monomania, the mind is concentrated upon one object or train of ideas, whatever it may be. The patient displays infinite resources to justify his error, and applies the most imperturbable attention in pursuit of it.

27. Disorders of the passions, and more especially of the intellectual faculties, particularly characterise general or maniacal insanity; disorder of the affections chiefly mark partial insanity, the intellectual faculties being but little affected. It is in the former that the greatest

agitation is observed, many patients vociferating day and night, until their voices become, in a short time, so altered, that, in spite of their efforts, they cannot be heard at the distance of a few paces — a species of *aphonia*, peculiar to the maniac. Although this aphonia is partly caused by the efforts to cry, still it seems to be in some degree owing to the state of nervous influence, for some patients evince it from the very accession of their malady. Some maniacs present the peculiarity of repeating all their actions, questions, or expressions, or even their discourses, a certain number of times. The simple repetition of these acts or expressions has been referred to a want of harmony in the action of both hemispheres of the brain; but the repetition is sometimes oftener than once.

28. Amongst maniacs are found instances of erotic excitement, of an exaltation of parental or filial affection, or of the ties of friendship. Some are ferocious, others quarrelsome, others have a propensity to murder, or to steal; and many are remarkably cunning and deceitful. All large establishments contain maniacs of pride; princes, sovereigns, great dignitaries, and even gods themselves, are not rare. Vanity is observed in all its extravagances, furnishing the best lesson to the vain fools who strut their hour on the stage of modern society. Here are found patients a prey to the most distressing anxiety, to the utmost mental agony; seeing in the present and in the future nothing but despair, imploring death, and desirous of inflicting it upon themselves, in order to escape from their miseries. Some dream of nothing but change, of distant journeys or voyages; others have lost their memory of persons or of things; and several, particularly during the exacerbations of the disease, can no longer speak their own language, but give utterance instead to confused and fantastical sounds, delivered in the tone of a continued discourse. Painters, musicians, and artists of all kinds, appear among those whose education has not been directed to the arts; and even poets, or, at least, rhymers, spring up amongst those who even have not learnt to read. Visionaries of all kinds abound; some apply themselves incessantly to the solution of the greatest problems of nature, or of the most difficult questions in metaphysics, religion, politics, political economy, &c., although uneducated; and prophets, saints, and martyrs are not uncommon.

29. Ought it to be inferred from all these varieties, as regards the intellectual disturbance, that each of them is connected with an isolated and distinct lesion of a particular part in the brain? Ought we, in the present state of our knowledge, to admit that the organ of the understanding is composed of an assemblage of particular and distinct organs for each propensity, and for each endowment? Ought we, in fact, to adopt, to its full extent, the psychological system, according to which these questions are answered in the affirmative? It would be out of place here to discuss the real value of a psychological system; but it becomes necessary to notice the assertions of those authors who maintain that, in partial insanity, particular forms of the skull correspond with the varieties of the mental affection; that they are able even to trace the propensities, the talents, dispositions, and dominant ideas of their patients. However, impartial observation of the insane, as M. FOVILLE very justly remarks, does not confirm the accuracy of these assertions. This writer, whose experience is most extensive, and powers of observation very great, states, that it is certain, that the same partial delirium, in many patients, corresponds to opposite forms of the same part of the skull. In some religiously insane, he has found the superior and middle part of the cranium remarkably developed, whilst, in others, the same portion was much below the ordinary magnitude. The insane who suppose themselves kings, emperors, princes, &c., are far from presenting, generally, a marked development of the regions of the organs of ambition, domination, vanity, &c., as assigned to them in the system of GALL, but are often inferior in this respect to those who pass the whole day in sweeping or cleaning the courts, &c., or who are most interested in the most menial occupations. If there exist distinct organs for every faculty or propensity, it is not necessary, I admit, that their development should be at all extraordinary, in order that irritation or inflammation should excite their activity, or occasion prominent or peculiar phenomena as respects them. But it may be stated, at once, that we often find, in cases of partial insanity, lesions as extensive as in those where the mental disorder was general; and that we occasionally observe instances of partial delirium, that cannot be the result of the excessive, or of the irregular, exercise of any fundamental faculty, or of vascular disorder limited to any particular part of the brain, to which such partial affection may be referred, even by those who espouse the doctrines in question. To the lesion of what fundamental faculty does the insane notion of a man correspond, who believes himself changed into a woman, *et vice versâ?* or of a person who believes himself transformed into a dog, assumes his habits, barks like him, walks on all fours, bites, &c.?

30. It may be truly said of partial insanity, that whatever, in the course of a man's life, may be to him an object of a particular regard or propensity, of a distinct taste, of a ruling passion — all the bizarre or fantastical ideas which his mind may entertain, may, in a state of disease, become the subjects of his delirium or hallucination; that many delusions — many forms of partial insanity — cannot really be referred to lesion of a particular faculty, or of that portion of the brain which has been considered the origin of such faculty; and that, in short, where it appears reasonable to refer them to an alteration of this kind, attentive examination of the conformation of the skull is far, in the majority of cases, from corresponding to the assertions of the authors of the psychological system in question. It must not, however, be inferred from what has just now been advanced, that attentive observation of the forms of the skull of the insane is of no use; on the contrary, a regularly developed cranium, of a reasonable size, ought, *cæteris paribus*, to assist an opinion, as to the possible issue of the disease, very different from that inferred from a small, confined, and deformed skull. What has been stated applies only to the assumed seats of fundamental faculties, exclusively or principally affected in certain patients. In short, the disorders of the intelligence in the insane are partial or general, as regards the intellectual faculties, properly so called, and likewise in respect of the passions and affections.

31. In a very great majority of cases the insane are unconscious of the state of their minds, and are offended at being considered mad. They even accuse those of insanity, who do not admit the integrity of their intellects. Some, on the contrary, are conscious of being deranged, but are unable, nevertheless, to correct the aberrations of their reason. These rare instances show what benefit may be expected to result from attempts to convince an insane person that he is deranged.

32. iii. THE SYMPTOMS FURNISHED BY THE LOCOMOTIVE ORGANS. — The disorders of voluntary motion in the insane may be divided into — 1st, Those which are temporary and local; and, 2dly, Those which are persistent and general. — *a.* In many, the movements become remarkably vigorous and energetic; an irresistible inclination to run, jump, gesticulate, &c. manifesting itself, produced by the general irritation, which occasions the mental affection. These, however, cannot be regarded as important or specific alterations; but sometimes, during the paroxysms of the alienation, the muscles of the face, or of an arm, or of a leg, are agitated by *irregular movements, like convulsions,* which are strictly local, are very distinct from the general convulsions of epilepsy or hysteria, and resemble the involuntary movements attending neuralgia. These irregular and convulsive actions of the muscles of a single part or limb are met with chiefly in the intermittent or paroxysmal forms of insanity, or in exacerbations of the disease; and are evidently dependent upon the morbid condition of the brain, from which the paroxysms or exacerbations of mania result. They are only occasionally observed, and were first described by M. FOVILLE.

33. *b.* An incomplete and *peculiar form of Palsy* is much more common in the insane than the foregoing local convulsive action, and is even much more serious. It is not mentioned by the older writers, and it is but slightly noticed by PINEL. M. ESQUIROL has studied it with much care, and especially with reference to the ulterior progress of the mental disease. More recently, MM. DELAYE, BAYLE, and CALMEIL have investigated it still further. This affection, usually designated the paralysis of the insane, and general or incomplete palsy, consists of a general and gradual loss of power in the voluntary muscles. It commences with an embarrassment of the motions of the tongue, or with indistinct articulation. Patients hesitate for a time at some syllables, which they overcome only by an effort. They are unable to pronounce some letters, — the R, for instance, — or they express them with difficulty. Afterwards a similar embarrassment is observed in the movements of the arms, legs, &c.; and lastly, in all the muscular system. The disorder possibly commences as early in the muscles of the limbs as in those employed in articulation; but as these latter require a greater precision of action for the due performance of their functions than the former, they more readily betray the incipient disorder, and this disorder is thus more early brought to the notice of the physician.

34. It requires, however, some experience to enable the physician to ascertain the commencement or earlier grades of this affection. When it has made some progress, the diagnosis is easy. The embarrassment of pronunciation is then very sensible. The patient cannot speak without throwing all the muscles of the face into action. The walk is vacillating; the motions of the arms and hands are unsteady and awkward,—and these last constantly tremble, and are incapable of retaining a determinate position. It is not, however, as yet, the force, so much as the precision, of the movements that is impaired. A patient may squeeze any object with much power, but he cannot execute any delicate work, or even button his own vestments. In attempting to run, his course is irregular, or attended by deviations to the right and left, like to an intoxicated person; he exhibits the appearance of suppleness, but a state of morbid tension exists in all the muscles of the trunk, extremities, head, and face; he comes awkwardly down on the soles of his feet, his arms are extended, the eyelids are widely open, the jaws firmly closed. Sensibility becomes blunted, so that irritation of the skin is not perceived until after some time. The paralysis of the insane is often more marked on one side of the body than on the other; but sometimes the progress of the affection varies, or even alters materially in either side.

35. *c.* If this complication be observed with attention, *two distinct stages* may be recognised: — In the *first*, the movements, although uncertain, retain a certain vigour — a rigidity of action, rather than power. This gives way, after a time, to the *second,* — to a relaxation — or a state of resolution, always increasing, of the muscular system. The patient becomes incapable of exertion; the features sink; the eyelids open sluggishly; the eye is dull; the jaws fall; the lips are pendant; and the excretions are involuntary. The patient is incapable of retaining a favourable position, and at last lies prostrate; the parts pressed upon by the weight of the body being excoriated, and ultimately gangrenous. In the course of this state of disease, attacks of cerebral congestion, followed by convulsions and coma, which continue for many hours, and are frequently repeated for several successive days, are often observed. After these attacks, the intellectual debility and aberration, and the paralysis, which are generally coordinate, are much more prominent. In many, variable periods, during which the symptoms are stationary, are interrupted by seizures of this kind, after which the malady proceeds rapidly, without ever retrograding, until the last degree of intensity is reached.

36. In the great majority of those who experience this complication, the paralysis does not commence until after the appearance of the intellectual disorder; but in some the insanity and palsy appear simultaneously; and in a few the muscular affection precedes the mental derangement. It should, however, be kept in recollection, that a general paralysis, similar in all respects to that now described, occurs, in rare instances, without being followed by insanity. I have seen several cases of this kind; and the circumstance has likewise been noticed by MM. DELAYE and FOVILLE.

37. iv. THE PHENOMENA EXHIBITED BY THE ORGANIC FUNCTIONS. — These functions present but little that is determinate, although they are rarely observed in a truly healthy state. Digestion is usually disordered in the earlier periods of insanity. The appetite is deficient or altogether lost; and more or less thirst is present. The mouth is clammy, and often dry; the tongue is white, with the papillæ often erect, or it is loaded

or slightly furred, or covered by a slimy mucus. It is often red at its point and edges. The salivary secretion is commonly scanty or frothy, but in a few instances it is increased, or frequently rejected. The *bowels* are more or less constipated, and the *urine* somewhat coloured. These symptoms very often disappear under an appropriate treatment, the mental disorder continuing even without material change; and the appetite returns, or is even increased. Sometimes the appetite is excessive from the commencement, although the other symptoms just mentioned are all present. Costiveness is the most general and persistent symptom, often continuing through the whole course of the malady.

38. The *pulse* is sensibly accelerated in the majority of cases. Authors have erred remarkably — even recent writers copying the blunders of those who have preceded them — in saying that the disease is unattended by any disturbance of the pulse. Rush found the pulse affected in seven eighths of his cases; and M. Foville observed a large majority of cases of uncomplicated insanity, with more or less acceleration of pulse, the mean pulsations in those examined by him being 84 in the minute. In comparatively few the pulsations were under 70, and in none were they below 60. The *heart's* action is attended by increased impulse in the majority of cases; and in a few it is tumultuous, irregular, or even intermittent. In some it is weak, and almost inaudible, or insensible to the touch. Organic change of the organ, in some one or other of its numerous kinds, is very common, especially in old cases of insanity. M. Foville states that he found some alteration or other of the heart in five sixths of the cases of insanity that he had examined after death during three years. But these changes are accessory, or not necessarily connected with the mental disorder: they are even, in many cases, produced by it.

39. v. Accessory Symptoms. — In all recent and acute, as well as in all prolonged cases, in which the symptoms have retained or assumed an acute character, obstinate *insomnia* is generally present. I have seen it often precede the mental disorder; and where the insanity presents an intermittent or paroxysmal form, it attends the accessions. This symptom is frequently most remarkably obstinate and prolonged; insane patients sometimes passing weeks or even months without the least sleep. When sleep is obtained, it is disturbed, dreaming, or wandering, or even raving. As to the symptoms furnished by the external aspect of the body, but little can be stated, as they vary with the habits and conditions of the patients, and the stages of the malady. In the great majority of cases, the expressions of the countenance correspond with the nature of the ruling passions, which manifest themselves with so much the more energy and truth, as nothing counteracts their operation. The eyes are unfixed, unsteady, wild, or timid, and incapable of returning a determined or steady look. The conjunctiva is injected, and the conchæ of the ears more or less red. The cheeks are not always coloured similarly to these two parts; for they may be either pale or red, or livid, whilst these present the highest degree of vascular injection. The skin is hot and dry, or hot and moist. The heat is greatest and most constant over the forehead, the extremities being frequently at the same time cold.

40. The co-existence of some important affection of the digestive, circulating, and respiratory organs with insanity sometimes imparts to the latter a modified or intermittent form. It is not rare to see phthysis breaking out during the progress of the mental disorder, and suspending it for a time. The patient in this case recovers his reason, whilst the pulmonary disease makes progress: but if this progress is arrested, the insanity returns; and these alternations often succeed each other until death takes place. Frequently an acute disease supervenes upon, and interrupts the course of, insanity, which reappears in all its severity after the accidental omplication has subsided. M. Foville thinks that this effect is oftener produced by acute inflammations of the chest than by those of the abdominal viscera. And lastly, an acute disease, thus occurring in the course of the mental affection, sometimes entirely suspends the latter, and is followed by complete recovery.

41. On passing in review the principal symptoms of mental alienation, disorders of the intellectual and moral powers only will be found constant. These disorders will often exist in persons whose sensations and movements are performed as regularly as in health; but they will also be frequently associated with morbid sensations, false perceptions, and delusions. In this latter case the conversation and actions of the insane will be as much the results of these sensations and perceptions, as the discourse and actions of reasonable persons are the results of external circumstances and rational inferences; the intellectual disorder then truly appearing to be chiefly the consequence of the affection of sensation and of perception. Where the mental alienation is associated with disorder of the voluntary movements, the connection between both is very different from that existing between the former and the sensations and perceptions. The voluntary movements are disordered as a contingent consequence of the lesion of the brain, that either is caused by, or occasions, the mental disorder; and are hence merely a complication, but one indicating a hopeless state of the malady. Lesion of voluntary movements, as described above (§ 32.), may, in rare cases, exist without insanity, but is generally consecutive upon, and an occasional complication of, disorder of the perceptions, or of the intellects, or of both the perceptions and intellects. This complication, moreover, merits the strictest attention in practice; for, where it exists, the perceptions and faculties are not merely simply perverted, but are, with the sensations, weakened, or even blunted. The memory is impaired; and association of ideas, whether true or false, is no longer vigorous. The affection of the intellects assumes an analogous state to the disorder of voluntary motion; the mental powers, as well as the muscles of volition, are universally weakened, and ultimately paralysed.

42. It is evident that the proportion of cases in which the mental disorder is simple, and of those in which it is associated with lesions, either of sensation and perception, or of motion, or of both, must vary with the numerous circumstances connected with the predisposing and exciting causes, and with the duration and treatment of the malady; that the proportion of each class in lunatic establishments, especially, will vary with the regula-

tions by which they are governed, and particularly with the restrictions as to the kind of cases admitted, the duration of the malady previous to admission, and the continuance of the patient under treatment. On this point, therefore, no precise information can be adduced. M. FOVILLE, however, states, that in an institution containing 334 insane persons, of whom 144 were men and 190 women, he found 214, of whom 94 were men and 120 women, presenting intellectual disorder without complication; 89, of whom 34 were males and 55 females, manifesting various disorders of sensibility; and 31, of whom 22 were men and 9 women, labouring under general paralysis. According to this account, the number of cases of simple intellectual insanity is the most considerable; the proportion of cases associated with deranged sensibility and perception, somewhat greater in females than in males; and the number of those complicated with general paralysis, was much greater in men than in women.

43. II. ARRANGEMENT OF MENTAL DISORDERS. — It is not more easy, satisfactorily to arrange the disorders of mind, than, in many instances, to determine the presence of disorder, and especially of that which is more strictly moral, the existence of which, if not always questioned, has been very generally overlooked, until contended for by a few recent authors.

44. The ancients divided insanity into *Mania* and *Melancholia*. By mania they understood a general delirium, and by melancholia a partial delirium. This division has descended down to a recent period, receiving, from time to time, some modifications, which have not prevented its being still adopted by some modern writers.

45. M. PINEL arranged mental diseases into — 1st, *Mania*, which he defines a general delirium with agitation, irascibility, and a propensity to furor; 2d, *Melancholia*, or exclusive delirium, with debility, moroseness, and a propensity to despair; 3d, *Demency*, or a particular debility of the operations of the understanding, and of the acts of the will; and, 4th, *Idiotism*, or a sort of stupidity more or less marked, with a nullity of character, and a most limited circle of ideas.

46. Dr. RUSH, in his excellent treatise on diseases of the mind, divided them into *partial* and *general*. He subdivided the *former* into — 1st, *Tristimania* (hypochondriasis and melancholia), in which a person entertains false ideas respecting his person, his affairs, and his condition, whereby he may be plunged in despair; and, 2d, *Amenomania*, in which the delirium is lively. The *latter* he subdivided into — 1st, *Mania*, or violent general delirium, with propensity to furor; 2d, *Manicula*, or a milder form of the preceding, or a chronic state of it; 3d, *Manalgia*, or a general torpor of the body and mind; 4th, *Dissociation*, or a state similar to the Demency of *Pinel*; and, 5th, *Fatuity*, or a condition generally denominated Idiotism by French nosographists.

47. M. ESQUIROL arranged mental disorders into — 1st, *Mania*, general delirium; and, 2d, *Monomania*, partial delirium. The term monomania conveys a clearer idea, and one more applicable to the diversity of cases of partial insanity, than the word melancholia. He applies, with great propriety, the term *idiotism*, or idiotcy, to congenital abolition of the mental faculties, and that of *dementia*, or *demency*, to accidental loss of them. M. GEORGET, adopting the division of ESQUIROL, added a fifth species, consisting of acute dementia, described by the latter as a variety only.

48. GALL endeavoured to connect the states of partial insanity to the respective fundamental faculties into which he divided the manifestations of mind. His pupil, SPURZHEIM, whilst he kept in view the doctrines of his master, admitted four states of insanity: viz. idiotism, dementia, alienation, and irresistibility.

49. Dr. M. BURROWS, extending the signification of the word insanity beyond most of his predecessors, has divided it into — 1st, *Delirium — delirium tremens*; 2d, *Mania — puerperal mania*; 3d, *Melancholia — suicide*; 4th, *Hypochondriasis*; 5th, *Demency*; and, 6th, *Idiotcy*. He observes "that delirium and hypochondriasis have better claims to be considered as distinct species than mania and melancholia. It is true that, if delirium be received only in its ordinary acceptation, as symbolical of intellectual disorder, it does not merit the rank of a distinct malady. But I think that there is ground to consider it as a frequent idiopathic affection, though certainly much more generally as sympathetic, and often as symptomatic." On this topic it is unnecessary to offer any remarks, or to do more than to refer the reader to what I said when discussing the *diagnosis* of DELIRIUM and HYPOCHONDRIASIS.

50. Professor HEINROTH has furnished a very elaborate arrangement of disorders of the mental faculties in his able work. He considers the derangements of the mind to be limited in number and in kind only by the diversities of the mental manifestations; and he bases his classification of these disorders upon two distinctions: the *first* is the difference which consciousness shows to exist in our mental operations; or which exists between — 1st, the feelings or sentiments; 2d, the understanding or reasoning powers; and, 3d, the will. The emotions of joy, grief, pleasure; the processes of reflection and contemplation; and the acts of the will or of self-determination; are *three* kinds of mental phenomena, which he considers to be so clearly distinguished from each other, as not to be confounded. According, therefore, as the cause of insanity is in relation to one or other of these kinds of mental manifestation, or as the disorder refers itself to either of these, or as it affects the feelings, the understanding, or the will, so it is placed in his classification, which consists of three classes of mental disorders, corresponding to these three departments of mental operation. The *second* distinction is derived from the character of the disturbance — whether it is that of exaltation or depression — of increased or diminished excitement or action.

51. Conformably with these bases of arrangement, the FIRST DIVISION consists of *disorders of passion, feelings, affections, and moral dispositions*: and presents *two forms*, viz. 1st, Of *exaltation*, or excessive intensity, giving rise to undue vehemence of feeling and morbid violence of the passions and emotions; and, 2dly, Of *depression*, or simple melancholy, or dejection without illusion of the understanding. The SECOND DIVISION comprises *disorders of the understanding or intellectual faculties*, consisting of two forms, the first of which is characterised by *exaltation*, or undue intensity of the imagination, producing mental illusions, or the several varieties

of monomania; the second, by *depression*, or feebleness of conception of ideas — by imbecility of the understanding. The Third Division consists of *disorders of the voluntary powers*, or of volition and the propensities; — the first form of which is characterised by *violence* of will and of propensity, or madness without lesion of the understanding; the second, by *weakness* or incapacity of willing, or moral imbecility. To these unmixed forms, Dr. Heinroth adds, under each division, others displaying combinations of several simple varieties. Thus, exaltation of feeling and of imagination constitutes derangement of the understanding with violent excitement or raving madness: delusion, with depression of feeling, constitutes insanity, with sorrowful dejection, or melancholy, &c.

52. M. Guislain, in his first able work on mental alienation, adopted, with very little change, the arrangement of Pinel. But in his more recent treatise, he has taken a more comprehensive and more original view of morbid mental affections, upon which he has bestowed the name *phrenopathies*, and which he has considered to proceed from an *exaltation*, or an *aberration*, or an *oppression*, or even from *exhaustion*, of the cerebral energies. These are the *four pathological conditions*, which he views as the *efficients* of mental disorders; and he arranges them as follows, — comprising, however, several affections not usually included amongst mental diseases, although sympathetically, or even more intimately, deranging the manifestations of mind: —

53. i. *Melancholia* or *Luperophrenie* (from λυπηρὸς, sad, and φρὴν, the mind), which he defines to be an exaltation of the feelings and sentiments to a state of sadness, and which he considers to exist at the commencement of almost all cases, and, with lesion of the sensibility, to constitute the fundamental character of insanity, appearing as one of the more important features of the malady. It frequently, however, assumes a monomaniacal, or, as he more correctly terms it, *monopathic*, form (from μόνος, single, and πάθος, disorder).

54. ii. *Mania*, or *Hyperphrenie* (from ὑπὲρ above, and φρὴν), which he views as a state of cerebral reaction, in which the whole or some of the active manifestations of the intellect, or traits of the character, or propensities, &c. are remarkably exaggerated and disordered. This species of insanity presents two states; — that of *erethism*, or tranquil mania; and that of *orgasm*, or furious mania. It may be partial — *monopathic*, or *monomaniacal*; or more or less general, as respects the extent to which the instinctive, intellectual, and moral powers are implicated. It may thus appear in the shape of ambitious, religious, lascivious, covetous mania, &c., assuming either a tranquil or a more or less furious character. The different forms of this species may be *associated* with *melancholia*, constituting *melancholic mania*.

55. iii. *Madness*, or *Paraphrenie* (from παρὰ, along with, and φρὴν), which he defines to be cerebral reaction characterised by fantastic aberration. This species presents numerous varieties and modifications as to the extent and association of mental disorder. But it is frequently partial or monopathic, and it may be either of a harmless or destructive nature. It is often *associated* with *melancholia*, or with *mania*, or with *both*.

56. iv. *Extasis*, or *Hyperplexie* (from ὑπὲρ, above, and πλῆξις, astonishment), which he views as sub-convulsive reaction of the cerebral power, characterised by immobility and rigidity. This state, although often monopathic, is also frequently complicated with *melancholia*, or with *mania*, or with *madness*, or with any two, or even all, of these.

57. v. *Convulsions*, or *Hyperspasmie* (from ὑπὲρ, and σπασμὸς, violent contraction). This species M. Guislain defines to be reaction, with muscular and mental agitation. He comprises under it tremor, convulsive syncope, chorea, hysteria, and epilepsy, — disorders previously not similarly classed, although either of them often *complicates* one or more of the mental disorders already enumerated, and even all of them, in rare instances.

58. vi. *Delirium*, or *Ideosynchysie* (from ἰδέα, idea, and σύγχυσις, confusion), which he states to be reaction and aberration of the ideas, wandering of the intellects, illusions, hallucinations. This may be *monopathic*, as when the patient is possessed by a single idea or illusion; or it may be *associated* with one, or more, or even with all, of the mental affections just noticed.

59. vii. *Incoherence*, or *Rêvasserie*, or *Anacoluthie* (from ἀνακόλουθια, incoherence). This state M. Guislain considers as different from delirium, inasmuch as in the latter the ideas run upon some illusion or hallucination, whereas in this state they arise vaguely, and without any connection with each other, or with any particular subject or object: nothing is expressed clearly or consecutively. In delirium, the idea, although false, presents some connection, or even the colours proper to it. Incoherence may be *monopathic* or *associated*; most frequently the latter; and the association may be with either of the preceding affections, or with several of them.

60. viii. *Dementia*, or *Noasthenie* (from νόος, intelligence, and ἀσθενία, debility). This state is viewed by M. Guislain as one of mental prostration and incapacity, in which the mental powers are palsied. This species is made to comprise those forms of insanity which consist of various grades of imbecility, original or acquired — congenital idiotcy and senile fatuity. Like the preceding species, it is either *monopathic* or *associated*, more frequently the latter, in which state it is usually the consequence of chronic or greatly prolonged forms of the disorders already enumerated.

61. I have thus fully adduced M. Guislain's arrangement of mental disorders, because it presents not merely a classification, but also an instructive analysis of them, especially when attentively considered in his own copious exposition. For practical purposes, and for the inexperienced practitioner it will be found deficient in simplicity: but coming as it does from one of the most experienced and ablest writers on mental alienation, it deserves our careful attention and our respect.

62. M. Foville, in attempting a physiological arrangement of mental disorders, observes, that *three orders* of phenomena, sensations, intellectual combinations, and movements, succeed one another in the actions of the nervous system; and that three orders of symptoms, exactly corresponding, show themselves singly or combined, in mental diseases. In founding upon the existence of the symptoms of a single one of these orders, and upon the successive appearance of those of the other two orders, he hopes to have laid, not only a physiological, but also an ana-

tomical basis of classification for the principal divisions of mental alienation, inasmuch as he thinks it may be admitted, at least with the consent of many modern writers, that sensibility, movement, and intelligence have each their distinct organic seat, although dependent upon the same system.

63. As *disorder of the intellects* is the most constant, the particular instances in which it is alone present constitutes M. Foville's *first division*, which comprehends mania, monomania, demency, and idiotcy, without complication with false perceptions, or with any disorder of the muscular system. In the *second division*, he arranges all cases characterised by the coincidence of disorder of sensation and perception with derangement of the intellects; and, in the *third division*, he comprises those which manifest that disorder of the muscular system, usually denominated general paralysis, or the palsy of the insane. In this third class he also comprehends the epileptic insane, as well as idiots, whose limbs are wasted and paralytic.

64. Dr. Prichard has distinguished insanity into — 1st, *Moral*; and, 2d, *Intellectual*: the latter he has divided into — (*a*) *Monomania*, or partial insanity; (*b*) *mania*, or raving madness; and (*c*) *Incoherence*, or dementia. *Idiotcy*, or mental deficiency, he has considered as entirely apart from, or unconnected with, any form of mental alienation.

65. Dr. Mayo, in his *Pathology of the Human Mind*, divides primary mental disease into — 1st, *Perversion*, or insanity; and, 2d, *Deficiency* of the mental manifestations. He subdivides *Perversion* of mind into — 1st, *Moral* incoherency; and, 2d, *Intellectual* incoherency: and *Deficiency* into — 1st, *Brutality*, or absence of the moral faculty; and, 2d, *Imbecility*, or intellectual deficiency.

66. I shall not notice at greater length the divisions of the various forms in which mental disorder presents itself, that have been attempted by modern writers. Enough has been advanced to show the difficulty of the attempt, and to prove even (what many would endeavour to conceal) that one form of mental disorder gradually and insensibly passes into that more nearly allied to it, not only in distinct cases, but often also in the same individual: that, for instance, partial, may rapidly pass into general, insanity; that melancholia may quickly pass into mania, or mania rapidly lapse into melancholia, or that both may very frequently alternate; and that the more simple states of intellectual disorder may be soon associated with disorder of the sensations and perceptions, or be still further complicated with lesion of the movements, in the form either of general palsy, or of epilepsy, or even of both. Nevertheless, although even the most different forms of insanity more closely approximate than is generally imagined, still it becomes necessary to preserve and to recognise such distinctions between them as really exist, inasmuch as they furnish most important indications for moral as well as for medical treatment. In the division, therefore, which I shall attempt, I shall endeavour, at the same time, to point out close relations as well as obvious distinctions; and to follow the progress of mental disorder from its more simple, partial, and common forms, up to its more general and complicated states. Conformably with this intention, I shall take a brief view — 1st, of the Partial Forms of Insanity — (*a*) as evinced chiefly in the *moral manifestations* of mind, and (*b*) as affecting principally the *understanding* or *judgment*; — 2d, of the General Forms of Insanity — (*a*) in the state of *mania*, or raving madness; (*b*) in the states of *incoherence* and *imbecility*, or dementia; (*c*) in the state of *fatuity*, or annihilation of the powers of mind; — 3d, of Complicated Insanity — the insanity being associated (*a*) with *paralysis*, (*b*) with *epilepsy*, (*c*) with *apoplexy*, &c. — Connate and Puerile Insanity — *congenital privation of mind*, or *Idiotcy*, and *Puerile Imbecility*; Puerperal Insanity — *insanity during uterogestation, after parturition, and during lactation*; and Suicidal Insanity — *or suicide in relation to insanity*; will be considered in separate chapters of this article.*

---

* The following *classification* of the manifestations and affections of mind, with reference to their influence in causing mental and corporeal disorder, was published some years ago by the author. It may be found of use in considering the different forms of mental disorder, especially in relation to their arrangement, to their causation, and to their moral management. This classification of the affections of mind is based upon the relations of the human species to the rest of the animal creation, especially in respect of those manifestations which are exhibited by the higher animals. The *Instinctive Desires and Feelings* form the First Class, as being the most generally extended; and the *Intellectual States* and the *Moral Emotions* constitute the Second and Third Classes, as belonging especially to man, and as furnishing him with a numerous class of ideas, which raise him above all other animals, which ennoble him in his social and moral relations, and which enable him to derive advantages from the past, to rationally enjoy the present, and to form the liveliest hopes, and even the firmest anticipations, of the future.

CLASS I. Instinctive Desires and Feelings. — Strong and immediate incentives to action in the lower animals, but controlled by reason in man.

Order I. *Instinctive Feelings, tending to preserve the Individual.*

a. The *sensations* derived through the medium of the external senses contribute to the preservation of the individual, by showing him what is injurious, and by enabling him to supply himself with what his internal sensations or appetites indicate to be necessary to his existence. — *b.* The appetite for food and drink. — *c.* The desire of preserving the animal warmth. — *d.* The desire of repose. — *e.* The desire of place. — *f.* The desire of pleasure and the dread of pain. — *g.* The desire of continued existence.

Order 2. *Instinctive Desires tending to perpetuate the Species.*

a. Parental and filial affection. — *b.* The desires of sex. — *c.* Desire of society and social feelings, giving rise to mutual support.

The *sensations* and *desires* are most powerful incentives of volition. — The appeasing of the *desires* is necessary, not only to health, but even to existence. The inordinate gratification of them is most injurious to physical and mental health, — is amongst the most fruitful sources of disorder of both mind and body.

CLASS II. Intellectual Powers, or States of Mind.

Order 1. *Powers of Consciousness, or the simple Intellectual States of Mind.* — Injurious to health, chiefly from their injudicious or excessive exercise.

a. Perception. — *b.* Attention — effects of protracted, to a single object, or train of investigation. — *c.* Conception — accurate or inaccurate views — their effects. — *d.* Memory. This last power is more or less concerned in a large proportion of the states of mind affecting the health.

Order 2. *Powers of Intellection, or the more active Intellectual States of Mind.* — The excessive exercise or misdirection of these is more or less injurious to mental and bodily health.

a. Simple suggestion or association of ideas. — *b.* Habit. — *c.* Imagination — its activity as influenced by the moral emotions of mind, sometimes beneficial, but oftener injurious to health. — *d.* Judgment, or reasoning. — *e.* Abstraction.

Order 3. *Ideas of Reflection, springing from the Exercise of the two former Orders of Powers.* — Rational incentives to action.

67. III. Of the special Forms of Insanity.— In the above general description, I have confined myself to the more obvious and fully developed states of mental disorder. It is necessary, however, that I should consider, in a more minute, yet succinct, manner, the specific forms in which aberrations of mind present themselves in practice, and more particularly those slight, moral, and partial states of disorder, to which I have as yet very imperfectly adverted.

68. i. Partial Insanity — *the simpler forms and slighter grades of mental disorder.* — Most authors have erred in viewing the more partial, or *slighter forms* of insanity, as consisting of derangement of one, or of a few, merely, of the intellectual or moral manifestations; or of a false perception, or delusion, by which the mind is constantly haunted, whilst the other faculties are unimpaired. I have already hinted (§ 3.) at the inaccuracy of this view; and stated that, although a single faculty or manifestation may be prominently disordered, or a single train of ideas be almost exclusively entertained, the other mental faculties are never in a healthy state, or very rarely retain their former energy. Conformably with this, the term, *partial insanity,* is not so applicable to the states of disorder about to be considered, as one which would imply a *slighter grade*, or a *simpler form*, of alienation. But as the former has been already employed by recent authors; and as it may be conveniently used, as implying slightness of grade, as well as an uncertain limitation as to extent; I shall retain it, and employ it synonymously with these expressions.

69. *A.* Moral Insanity— the *Monomanie sans Délire*, or *M. instinctive,* of M. Esquirol. — This state of mental disorder may be *defined* to be *a perversion of the natural feelings, affections, inclinations, temper, habits, moral dispositions or impulses, without any illusion or hallucination, the intellectual faculties being more or less weakened or impaired.* This state has been noticed by Heinroth and Guislain, and more fully by Dr. Mayo, M. Esquirol, and Dr. Prichard, in their recent works. Its earlier or slighter grades, however, have not generally been viewed as amounting to insanity; and, indeed, unless either the disordered manifestations, which I have just enumerated as constituting it, be remarkably prominent, or the intellectual faculties be much weakened or impaired, it cannot be really considered as amounting to mental derangement. Dr. Mayo has noticed, in his *Essay on the Relation of the Theory of Morals to Insanity*, a certain variety of it as belonging to insanity, and given it the name of *Brutality*. But in a more recent work he remarks, that further consideration has satisfied him, that to class it as such is loose and unphilosophical. He considers this as a distinct form of mental disease, especially in its fully developed or strongly marked form, and to be altogether distinct from the moral symptoms of insanity that occur at an early period of the disease, and that often afford, at that time, the only clue to its existence. By *Brutality,* — by the moral disposition to which this term may be applied, — he implies a destitution of principle; by *Insanity*, a perversion of tendencies and want of self-control. In the latter case, the patient cannot hear the voice of conscience; in the former, he has no conscience to hear.

70. The moral disorder, termed brutality by Dr. Mayo, is, however, only one of the modifications of moral insanity, comprised in the more extended definition which I have attempted to assign to this species of mental derangement, agreeably with the observations of Heinroth, Guislain, and Prichard; and is one arising

---

a. Mental identity. — *b.* Time. — *c.* Power. — *d.* Causation and truth. — *e.* Right and wrong. — *f.* Existence of a Deity. — *g.* Immortality of the soul. All these are seldom injurious to health, but are often beneficial in controlling the emotions and desires, in governing and directing the instinctive feelings, and in enabling the mind and body to resist the influence of injurious impressions and agents.

CLASS III. Moral Affections of Mind, *in which some of our Instinctive Feelings, as well as of our Intellectual Powers, are frequently more or less engaged.*

Order 1. *The Instinctive or simple Moral Emotions of Mind,* often sudden and violent incentives to action. When strongly excited, or much indulged, they are amongst the most influential causes of both mental and corporeal disease.

a. Anger, indignation, resentment, revenge — their effects upon health. — *b.* Sympathy — its effects. — *c.* Beauty, or deformity, — *d.* Love and hate, jealousy, domestic misery. — *e.* Pride, vanity, and humility — the liability of the former to lead to insanity. — *f.* Gladness, regret, sadness, and grief: — Grief from lost objects of affection — its effects — counteracted by progeny: — Grief from moral degradation the least supportable — why? Effects of sudden shocks of grief on sensitive minds. Disappointments of the affections: — Grief from loss of fortune, &c. Influence of repeated disappointment and losses — of harassing difficulties. — *g.* Hope and fear — their effects on health. Confidence. Various anticipations — their effects. Anxiety; — that of professions, particularly of medicine. Anticipated happiness — effects of the sudden arrest of, on sensitive minds, &c. Terror, fright, &c. — often productive of nervous diseases, and sometimes of mental disorder. — *h.* Gratitude. — *i.* Wonder. Desire of novelty. Mental languor. — *k.* Sublimity and ludicrousness. — *l* Love of approbation. — *m.* Desire of power and its related affections. Desire of Knowledge. Fame. Avarice.

Order 2. *Rational Emotions of Mind, arising out of moral and religious Obligations,* often strong incentives to action.

a. Rectitude, virtue, merit, and demerit, with all the duties we owe ourselves, as moral and responsible agents, and as tending to promote our intellectual and moral excellence and happiness. — *b.* Our various duties, as members of society. — *c.* Our religious obligations, as immortal beings. Remorse, or the consciousness of having neglected one or more of the above duties and obligations — sometimes productive of disorders of mind and body.

i. The influence of mental culture — intellectual and and moral — when duly directed in early life, upon the temperament and constitution, — upon mental and bodily health, — in developing and in strengthening both the mind and body.
ii. Temperament and constitution remarkably modify the operation of the affections of mind upon health. Illustrations.
iii. The influence of mental and bodily occupations — 1st, upon mind; 2nd, upon the body.
iv. Ill effects of want of occupation—Ennui—Hysteria—Hypochondriasis — Melancholy — Insanity — Suicide. Effects of solitary confinement.
v. Bad consequences of improper occupations and amusements, especially in females in early life. — Mental dissipation — its effects, particularly in impairing — 1st, Mental vigour; 2d, Bodily health.
vi. Consequences of habitual amusements, sensual indulgences, and pleasurable excitements, on the nervous system. These generate feelings calling for their repeated gratification, and for increased excitement, until nervous energy and vital power are exhausted, and until moral and physical ruin ensues.
vii. Good effects of a well-regulated and cheerful mind on health — of agreeable pursuits, particularly those exercising both the mind and the body. — The influence of confidence — of moderation — of contentment — and of agreeable and useful occupations, in securing both the health and happiness of their possessors.

chiefly from the unrestrained indulgence of the passions and appetites. To it, however, I shall more fully advert in the sequel. In respect of moral insanity, in its more extended signification, it is justly remarked by Dr. Prichard, that there are many persons living at large, who are affected, more or less, with this modification of mental disorder, and yet are reputed to be merely of a singular or wayward character. An attentive observer will often recognise something remarkable in their manners and habits leading to doubts of their entire sanity; and circumstances often appear which strengthen the suspicion. An hereditary tendency to madness may have existed in the family, or various members of it have been subject to diseases of the brain. The individual himself may have been the subject of an acute attack of insanity, or of inflammation of the brain, in a former period of his life; and from that time, or after having sustained some reverse of fortune, or the loss of a beloved relative, his temper and dispositions have undergone a change. This alteration of character may likewise have followed some dangerous illness or severe shock of constitution, especially fever, phrenitis, paralysis, apoplexy, or epilepsy. In some, the alteration in the temper, in the passions, the habits, or the disposition, may have been gradual or imperceptible; in others, sudden, or almost immediate upon its determining cause. In either case, it seems to have consisted chiefly of an exaltation of peculiarities or dispositions, more or less natural or habitual to the individual. In this state, a person may continue for years, following the bent of his perverse inclinations; always engaging in new pursuits, and soon relinquishing them, without any sufficient object or inducement excepting caprice. At length the total perversion of his affections, and dislike, or even enmity, to his dearest friends, excites alarm.

71. *a.* When the head of a family is affected with this ambiguous modification of insanity, it often becomes necessary, to prevent ruin from absurd extravagance or wild projects and speculations, to make some attempt at taking the management of his affairs out of his own hands; but for this the laws are inadequate, and the endeavour is often unsuccessful. Persons labouring under this disorder are capable of reasoning upon any subject within the sphere of their knowledge, and often display great ingenuity in giving reasons for their conduct, or in justifying their moral feelings. In these cases, as well as in others belonging to other modifications of this species of insanity, the feelings and passions are more or less excited, whilst the controlling faculties of reason and judgment — of attention and comparison — are equally weakened, errors in action and conduct resulting therefrom.

72. Moral insanity is not, however, limited to a preternatural excitement of the passions and temper, but comprises many other disordered states of the mind. Indeed, its varieties are almost as numerous as the modifications of disposition and temper. The most frequent forms are characterised, either by the kind of excitement just noticed, or by melancholy dejection. Either of these forms of moral disorder may continue more or less permanently; but they sometimes alternate or supersede each other, an opposite state of temper or feeling arising without any obvious cause. The prevalent character of the affection is occasionally derived from the natural disposition of the individual; but it is often remarkably different,— lively persons becoming dejected; and the melancholy or taciturn, lively, loquacious, or sanguine.

73. *b.* When *sorrow* or *gloom* is natural to an individual, and is not excessive, it does not amount to disorder; but, when it is remarkable and constant, without any real cause, it becomes a moral disease, although entirely devoid of any illusion or hallucination. Dr. Prichard remarks, that this tendency to morbid sorrow and melancholy, as it does not destroy the understanding, is often subject to control when it first arises, and probably receives a peculiar character from the previous mental state of the individual, from his education, and his religious or irreligious character. Persons of well regulated minds, when thus affected, express grief and distress at their conscious inaptitude to the active duties of life; and often feel a horror of being driven to commit suicide, or some dreadful crime to which they feel various obscure impulses or tendencies. This idea haunts them, and renders them fearful of being a moment alone. It, however, generally subsides, and a healthy state of mind returns. Persons of an opposite character frequently relapse into a state of *tædium vitæ*, or of morose disgust; loathe their very existence, and at length attempt to end it. A state of gloom and melancholy may, however, give way to a state of morbid excitement.

74. *c.* When the moral disorder is one of *unnatural excitement*, the person affected is full of projects and enterprises, or is active and boisterous, beyond the limit that belongs to a naturally lively disposition. This state of disorder may occur in persons whose temperament is the reverse of either the sanguine or lively; and it then becomes the more striking. It usually displays itself in a want of self-government, in continual excitement, an unusual expression of strong feelings, in thoughtless and extravagant conduct. A modest female becomes violent and abrupt in her manners, loquacious, impetuous, talks loudly and abusively of her friends or relations before entire strangers; or uses indecent expressions, and betrays, without reserve, unbecoming feelings and trains of thought. Persons thus affected often become drunkards; and a debauch is followed by raving madness, requiring restraint or confinement, which, with abstinence, removes, for a time, the maniacal excitement; but as soon as restraint is withdrawn, they resort to their former excesses, although well aware of the consequences. This form of the disease I have met with in two instances in professional men.

75. *d.* In examples of a different description, as Dr. Prichard remarks, the mental excitement constituting the disorder is connected with *religious feelings*, especially when the period of excitement has been preceded by one of melancholy, during which the person affected has laboured under depression and gloom, mixed with apprehensions as to his religious or future state. Formerly possessed by a dominant sense of condemnation and abandonment, when all hope and comfort have vanished, and nothing has mitigated the gloom and sorrow of the present, or allayed the dark and fearful anticipations of the future, his feelings become suddenly changed, and he

experiences a lively joy in his contemplations, amounting often to rapture and extasy. Such a change is hailed by the devout as a happy transition from religious destitution to divine acceptance and grace. But the train of excitement is too high, the expressions of happiness too extatic, to be long mistaken; pride and haughtiness, a violent or boisterous deportment, and selfishness, are soon betrayed, with want of natural affection, variability of spirits, and irregularity of mental habits and of conduct. In these cases, there is no false sensation or perception impressed upon the understanding; no illusion or belief of a particular sentence of condemnation, or message of acceptance, specifically revealed. If this existed, the case would be one, in which the moral disorder is only the consequence of a false perception or delusion, and consequently one which belongs to another species of mental disease.

76. *e.* Particular cases are marked, as noticed by PINEL, ESQUIROL, HOLLAND, and PRICHARD, by the prevalence of *certain passions* and *mental habits*, displayed under modifications, of which the human mind, in a sane state, seems hardly to be susceptible. Amongst these is an unusual prevalence of angry and malicious feelings, arising without provocation or ordinary excitement, constituting what PINEL designates, "*Manie sans Délire.*" There are many instances, observes Dr. PRICHARD, in which the whole diseased manifestation has consisted in a liability to violent fits of anger without cause, and leading to danger, or actual commission of serious injury to surrounding persons. The characteristic feature of this malady is extreme irascibility, depending on a physical morbid cause. There are other instances in which malignity has a deeper dye. The individual is continually indulging enmity and plotting mischief, and even murder, against some object of his malice. When this is connected with the false belief of some personal injury actually sustained, the case does not fall under the head of moral insanity. It involves hallucination or erroneous conviction of the understanding; but when the morbid phenomena include merely the expressions of intense malevolence, without provocation, actual or supposed, the case is strictly one of moral insanity.

77. *f.* In some instances, the *impulses* and *propensities* to which the patient is subject, or which he has indulged, are so exalted or disordered, as to constitute the sole manifestations of insanity, as ably insisted upon by REIL, HOFFBAUER, and PRICHARD. A sudden impulse to commit an atrocious act may arise in the mind of a person otherwise apparently sane, and in possession of his intellectual faculties; and be resisted by reason and self-control, on each of many occasions of its successive occurrence. At last the patient either may doubt his own powers of control, solicit the interference of his friends, and submit himself to restraint; or he may, at last, be unable to resist the impulse. In other cases, crimes have been perpetrated without any fixed object or motive, and the punishment of the law has overtaken the victim of disease. Insane persons may display their states of mental disorder by a propensity to commit every species of mischief, although devoid of any feeling of malevolence. A propensity to theft is frequently a feature, and often the characteristic one, of moral insanity. In some, it may be nothing more than eccentricity of character, as Dr. PRICHARD supposes, but it is more commonly associated with other manifestations of mental disorder, when actually amounting to moral insanity, and is to be viewed in connection with the individual's position in society, with his previous habits and character, and with the existence or non-existence of mental derangement in any member of his family.

78. *g.* *Moral Insanity* — the *Manie raisonnante* of PINEL — the *Monomanie raisonnante* of ESQUIROL — is often manifested, especially, by the singular, absurd, and exceptionable nature of the actions, intentions, and propositions of those affected by it. Persons thus disordered are turbulent, unsociable, and engaged constantly in affairs which are blameable, ridiculous, and contrary to their former habits, to their real interests, and to the interests of their families. Their moral character is altogether perverted, and they become dangerous chiefly to themselves and to those depending upon them, owing rather to the consequences, than to the nature, of the actions which they commit. Although engaged, or entering upon, what compromise their interests and character; or abandoning the objects of their affection, or quitting their families or affairs; they argue strongly in support of their conduct. Whilst there is a change or total perversion of the habits and affections, there is also sufficient power of intellect to attempt a justification of the sentiments and actions they have espoused.

79. *h.* Moral insanity has been viewed by M. ESQUIROL as presenting either an *acute*, or a *chronic* course; and he believes that it may be divided into *three stages*: — In the *first*, the character and habits are changed; in the *second*, the affections are perverted; and in the *third*, maniacal excitement, or violence of the temper or passions, with degradation of the faculties, more or less rapidly ensue. It may assume a remittent or intermittent course; and, after recovery from it, relapses are very frequent. If uncontrolled, it often passes into, or becomes complicated with, one or other, or even with more than one, of the other forms of insanity about to be distinguished, and even also with palsy.

80. *i.* The variety of insanity, termed *Senile Insanity* by Dr. BURROWS, as occurring in old age, often assumes the form of moral insanity, but more frequently that of general imbecility. In the former case, it consists in a morbid excitement of the passions, and a remarkable perversion of the temper and propensities — in a change in the whole moral character, without any hallucination or false perception, the existence of which would constitute it a different species of mental disorder.

81. A variety of instances, as Dr. PRICHARD observes, is mentioned by writers, in which the unusual intensity of particular passions or emotions has been thought to constitute mental disease, and compound epithets have been applied to these states of the mind and its affections. *Nostalgia*, and *erotomania*, have been considered as disorders of sentiment; *satyriasis*, and *nymphomania*, of the physical feelings. The excessive intensity of any passion is disorder in a moral sense. It may depend physically upon certain states of the constitution; but this does not so clearly constitute madness as the irregular and perverted manifestation of desires and aversions. This form of in-

sanity has undoubtedly been the source of moral phenomena of an anomalous and unusual kind, and of certain perversions of natural inclination, which excite the greatest disgust and abhorrence. Besides these, however, there are others, to which I may also more particularly advert, and which are noticed by M. ESQUIROL as constituting forms of monomania, under the designation of *Monomanie d'Ivresse*, of *M. incendiaire*, and of *M. homicide.* There may be doubts of the propriety of considering these, or even *erotomania*, as forms of insanity. But it is difficult, in respect of the mental manifestations, as well as of the bodily functions, to draw the line of demarcation between health and disorder; and there can be no doubt that the excessive excitement of any particular passion, sentiment, or emotion, or the undue predominance of it for an unusually long period, or the uncontrollable impulse or desire to appease or to gratify any appetite, amounts to moral disorder, which becomes the more manifest and indisputable, as it is the more freely indulged. As long as reason restrains the appetites, passions, and emotions, within the conventional limits prescribed in society, and is competent to the decided exercise of this sway, moral disorder cannot be said to exist; but when it loses this salutary influence, and in proportion as it is incompetent to exert such influence, either from the violence of passion, or the weakness of the understanding, the mental disorder is the more evident.

82. *α. Erotomania — Monomanie érotique* of ESQUIROL — is *characterised by an excessive love of some object, real or imaginary.* — It is a mental affection in which amorous ideas are as fixed and dominant, as religious ideas are in religious monomania or melancholia. Erotomania is very different from satyriasis and nymphomania. In the latter, the mischief is in the reproductive organs; in the former, it is in the mind. The one is a physical, the other a moral, disorder. Erotomania is the result of an excited imagination, unrestrained by the powers of the understanding; satyriasis and nymphomania proceed from the local irritation of the sexual organs, reacting upon the brain, and exciting the passions beyond the restraints of reason. In the former, there is neither indecency nor the want of chastity; in the latter, there is unrestrained expressions of sexual desire and excitement. The one is commonly caused by ungratified, or disappointed, affection excited in a virtuous mind; the other, by inordinate irritation or indulgence of the sexual passion.

83. In erotomania, the eyes are bright, the manner and expressions tender and passionate, and the actions free, without passing the limits of decency. Self and selfish interests are all forgotten, in the devotion paid, often in secret, to the objects of the mind's adoration. A state of extasy often occurs in the contemplation of the perfections which the imagination attaches to the subject of its admiration. The bodily functions languish during this state of moral disorder; the countenance becomes pale and depressed; the features shrunk; the body emaciated; the temper inquiet and irritable; and the mind agitated and despairing. The ideas continually revert to the loved and desired object; and opposition, or endeavours to turn them in a different direction, only render them more concentrated and determined in their devotion. At last, parents and fortune are abandoned, social ties broken asunder, and the most painful difficulties are encountered, in order to obtain the object of admiration.

84. In some cases, the attempts made by the patient to conceal and to overcome this affection, occasion a state of irritative fever, with sadness, depression, loss of appetite, emaciation, &c., which has not inappropriately been termed by LORRY *Erotic Fever;* and which, after continuing an indeterminate period, may even terminate fatally. When a young person becomes sad, absent in mind, pale and emaciated, sighs frequently, sheds tears without any obvious reason, is incapable of mental or bodily exertion, scarcely speaks to any one, loses appetite, &c., it is sufficiently evident that the mind is inordinately possessed by some desired object. If a strong effort be not made to dispossess it of the predominant sentiment, or if the object of desire be not obtained, the symptoms become still more distressing. The corporeal functions languish, the eyes sink, the pulse becomes weak and irregular, and the nights disturbed and sleepless. At last a form of slow hectic is produced; and the weaker organs, especially the lungs and heart, are the seat of slowly produced disease; the whole frame is blighted, and the patient sinks from the injurious influence of the mental affection on the vital organs.

85. This form of moral disorder may increase, and affect the intellects in a much more serious manner, until general insanity or mania is developed; and, with the progress of time, it may at last terminate in dementia or incoherent insanity. In each of these, the primary character of the disorder, or the original moral affection, will still continue to be manifested by the frequent suggestion of the same train of ideas, or recurrence to the object of devotion.

86. *β. The irresistible propensity to intoxication —Monomanie d'Ivresse* of M. ESQUIROL — may be viewed as actually constituting a variety of moral insanity, and indeed has been thus considered by the able and experienced writer just named. There can be no doubt of early advances of partial as well as of general insanity being sometimes indicated by an irresistible impulse to indulge in intoxicating liquors. And this impulse may be connected with a physical or corporeal feeling, rendering it still more irresistible, especially to persons of weak character. In many cases, indeed, the insanity is not so much caused by the intoxication, to which it is so frequently imputed, as the impulse to indulge it is a symptom of the incipient mental disorder. This is especially the case when a person, previously temperate, suddenly addicts himself to the use of intoxicating liquors, and particularly of ardent spirits. Sometimes, at the commencement of insanity, the state of the stomach, and even of the whole vital organs, is such as to be attended by an irresistible craving for stimulating fluids — by a kind of *pica*. This craving and the mental impulse accompanying it are generally suddenly developed; and occasionally, after having been appeased and gratified, they do not again return until after some time. Moreover, at this period of the mental disorder, the moral powers are weakened, and the mind altogether enfeebled and incapable of sufficiently resisting the morbid impulse, which is usually also attended by ennui, irritability, painful sense of sinking at the epigastrium, and restlessness. The desire to appease this

instinctive craving is, at last, imperative. When gratified, the patient becomes violent, maniacal, and dangerous to himself and to those around him. He continues to swallow the intoxicating fluids as long as he can procure them, or as long as he has the power of doing so, until the paroxysm terminates. As the patient becomes sober, the maniacal turbulence often subsides, but it frequently continues for some time afterwards, often for many days, with signs of more or less vascular excitement of the brain and its membranes; and, in many cases, when he can revert to the means of intoxication as he becomes partially sober, the insane violence is very considerably prolonged. At last the paroxysm terminates, and the craving for exciting liquors is no longer felt. Instances have even occurred of these liquors being afterwards loathed, until another paroxysm took place. M. ESQUIROL met with a case of mania consequent upon intoxication, which was followed by a distaste of all fermented and distilled liquors for ten years afterwards. Some persons, unable to withstand the impulse to intoxication occasioning fits of insanity, have solicited the restraint of friends; and others have committed suicide when they found themselves unable to resist the morbid impulse.

87. This state of moral disorder, whilst it gives rise to fits of maniacal excitement, aften also occasions more permanent mania, and even dementia. The maniacal paroxysms, when thus excited in females, are frequently associated with hysterical symptoms; and when mania or dementia is consequent upon it, palsy is not an infrequent complication.

88. *γ. Incendiarism is sometimes an act of partial insanity — Monomanie incendiaire* of ESQUIROL — *Pyromanie* of MARC. (*Ann. d'Hygiène*, t. x. Paris, 1833.) — It is, however, more generally one only of the modes in which an evil or mischievous propensity manifests itself, when excited by envy, jealousy, or revenge, in the minds of persons unrestrained by reason and by the laws. Yet instances are recorded by HENKE, ESQUIROL, MARC, and others, of persons being impelled to the commission of this act by an irresistible impulse, which their will was incapable of overcoming. Most of these cases have occurred in girls and young women, who were either pregnant, or disordered in the uterine functions. Several of them presented signs of increased determination of blood to the brain; and some manifested other signs of insanity, either with, or without, illusions or false perceptions. M. ESQUIROL concludes, from the history of cases of this kind, observed in France and Germany—1st, That mental alienation, whatever may be the character of the delirium, determines some insane persons to commit incendiarism; and, 2dly, That there is a variety of monomania without delirium (without hallucination) characterised by an instinctive impression — an uncontrollable impulse — to commit this crime.

89. *δ. Homicidal Insanity — Monomanie homicide*, ESQUIROL — *Fureur maniaque*, FODÉRÉ — *Manie sans Délire*, PINEL. — Murder, or attempts to murder, are made by insane persons — 1st, When impelled by an involuntary impulse, or instinctive desire, which they are unable to resist; 2dly, When actuated by motives on which they are capable of reasoning, and whilst conscious of the evil they have committed; 3dly, When influenced by illusions, hallucinations, or false perceptions; 4thly, When excited by passion or opposition; 5thly, When they believe that they are opposing an enemy, against whom they should defend themselves; and, 6thly, When the intelligence is so prostrate as to be incapable of distinguishing right and wrong, and when they act from imitation. It is respecting the *first* and *second* of these — the former especially — that I now proceed to offer a few remarks.

90. Persons who appear to enjoy reason, but whose active moral powers — whose affective functions of mind, in the language of French pathologists — are disordered, must, conformably with what I have advanced, be viewed as insane. These persons perceive, compare, reason, and judge correctly of matters, but they are influenced by the least cause, or even without any object, to acts of violence. They are irresistibly, or instinctively, impelled, with a full consciousness of their state, to commit the crime they most hate. They deplore their situation, and give warning to guard against their fury, or to deprive them of the power of committing the dreaded act.

91. But the question has been long since and often proposed — Is there really a form of insanity in which a person may enjoy reason unimpaired, and yet commit the greatest of crimes? M. ESQUIROL formerly answered this in the negative; and stated, that of the partially insane, who appear to enjoy their reason, and to deplore the determinations by which they are so strongly impelled, all admit that they have felt something internally or mentally at this time, of which they could give no clear account; that their brains were embarrassed; that they experienced more or less difficulty — often an inexpressible difficulty — in the exercise of their judgment; and that this was preceded by physical symptoms which they perfectly recollected. One felt a burning heat or a pulsation in the head; another, a lacerating or a sharp or acute sensation rising from the abdomen to the interior of the cranium; a third, a momentary illusion or hallucination; or a fourth was betrayed by an erroneous process of reasoning. One person suddenly becomes red in the face, imagines he hears a voice addressing him, and acts according to the injunction he believes imposed on him, or to the call addressed to him. A husband is persuaded that his wife is unfaithful to him; and, although every circumstance is considered by him, and found to militate against the truth of the persuasion, yet, in a moment when the jealous feeling gains the ascendancy, an act of murder is committed. The mother of a family believes that her situation is distressing, and that her children will be reduced to mendicity. In a fit of despair she forms the resolution of destroying them, in order to preserve them from a calamity which she considers greater than death; but in the moment of her attempting it, maternal tenderness, speaking louder than despair, exclaims, "Protect my children from me!"

92. All these instances may be referred to a momentary delusion or hallucination, under the influence of which crimes or insane actions may be committed, after which a lucid period occurs. But there are other instances which cannot be thus explained, and which do not altogether warrant the conclusion at which M. ESQUIROL arrived in his earlier work; and of this he is aware in his more recent production, for he there admits that,

although partially insane persons are often betrayed by their delirium or their hallucinations into the commission of homicide, yet there are others who commit the crime from an instinctive or irresistible impulse. In the former class of insane homicides, the understanding is disordered, under the influence of false perception, or of a delusion momentarily entertained, and the insane person acts under an error of judgment; but, in the latter class, reasoning and judgment are altogether suspended, and the insane impulse impels and directs the will, without any effort of the understanding or of the moral powers to prevent the act. An individual thus affected acts uninfluenced by delirium, or delusion, or emotion, or passion, and almost without consciousness, impelled by an instantaneous, blind impulse, independent of the will, and before which reason and judgment are for a moment entirely prostrate. This constitutes the paroxysm of monomania without delirium of the French writers. Of this affection I have met with three instances. In two of these, however, there was more or less disorder of the digestive organs; and in the third, a female, the catamenia were disordered; but there was no other indication besides this of mental alienation. This subject is most important, and is, moreover, very intimately related to *suicide*, inasmuch as the morbid impulse to destroy one's self is similarly manifested, as will be shown in the sequel, and much more frequently than the impulse to destroy another. Yet has it been nearly overlooked by most writers, and especially by those of this country, notwithstanding the growing increase of both crimes, and the evidence furnished, by a careful inquiry into their remote causes, of a progressive increase of them being likely to result. Homicidal monomania most frequently occurs in persons of a sombre, melancholic, or capricious disposition; but it is also met with in those who are remarkable for the amiability of their tempers and manners. The state of the atmosphere, disorder of the digestive and excreting organs, excitement of the nervous system, a vicious education, the reading improper books, and accounts of crimes, suicides, &c., unsound and exalted religious sentiments, the influence of imitation, chagrin and disappointment, want, &c., are chiefly concerned in developing this moral distemper. A very few instances from among many will illustrate this state.

93. The mother of four children was suddenly seized with the desire of killing them, and flew from her house as the only way of preventing the commission of the act. A maid, on each occasion of her dressing the infant committed to her care, was seized with an uncontrollable desire to murder it. A man experienced repeated impulses to murder his wife, to whom he was warmly attached, and was prevented on one occasion from attempting it by an accidental occurrence. He applied to the author for advice, and to be placed under restraint. He was at that time apparently well, and capable of pursuing his usual avocations. A person, after reading the horrible details of a murder, which was circumstantially narrated by the daily and weekly caterers to the most depraved passions of the multitude, was suddenly seized with an impulse to kill his wife. It has been observed in France, in Germany, and in England, that the publicity given to the particulars connected with a murder has been followed, within a few days, by several attempts to commit this crime.

94. Although various moral causes combine, in some cases, to predispose the mind to be influenced by the insane impulse to perpetrate this and other crimes, yet it will be found, in most, if not in all, instances, that the person thus *morally* affected is also *physically* disordered, if the examination be made with sufficient care, and with the requisite knowledge of the several manifestations of gradual and insidious disease of the brain and of the abdominal organs. A most attentive examination of the various functions of the brain and of the senses connected with it — of the temperature and circulation of the head — of the functions of those viscera which most readily sympathise with the brain, and which so powerfully influence both its actions and its circulation, and even of the appearances of the tongue, and of the several excretions — will generally disclose more or less disorder in one or more of these quarters, and prove, that although there may not be very obvious disease, there is lurking mischief, either primarily or consecutively, but always most seriously, affecting the brain. In the slighter and more incipient states of morbid action in this organ, the general and local sensibility and the circulation often betray little or no disturbance, and indeed the whole amount of physical disorder may be so small as to escape the detection of all, excepting the closest observer, who, from experience, will look for it, and detect it, more readily in the sympathies, and in the symptomatic affections, of remote parts, than in disorders of more closely related organs. It is reasonable to infer, that when capillary action in the brain is slightly but very generally disordered, and especially when this disorder commences gradually, and almost imperceptibly, and proceeds slowly and insidiously, those manifestations of mind which are of the highest order in the scale of mental development will be the earliest and most seriously deranged; and that, as the physical disorder proceeds or extends, the other orders of mental operation — the *intellectual* and the instinctive (see *Classification* at § 66.) — will become successively implicated, until the various phases of moral and intellectual insanity are passed through, and instinctive insanity, or fatuity, is ultimately reached.

95. *B.* PARTIAL DISORDER OF THE UNDERSTANDING — *Amenomania* of RUSH — *Monomania* of ESQUIROL — *is characterised by false perceptions, illusions, or erroneous convictions, referring to one or a few subjects merely, or involving chiefly a single train of ideas, and so impressing the mind as to partially disorder the judgment.* Partial insanity of the understanding may exist — 1st, *In a more or less simple form*; or, 2dly, *Associated, or complicated, with moral insanity.* Indeed, most of the instances in which crimes are committed in the insane state present this latter form. Even the more simple states of monomania of the understanding may be said to be insanity with reference to a small number of subjects, rather than to one subject only; since the number of persons who are insane upon a single subject merely is comparatively few. Most of the cases usually denominated monomaniacal are those which present some predominant idea, or hallu-

cination, amidst other indications of mental weakness or disorder, as I have already contended (§ 68.).

96. This species of insanity was distinguished by the term *melancholia*, from the age of HIPPOCRATES, till M. ESQUIROL imposed upon it the name of *monomania*. As the former expression suggested the idea that partial derangement of the understanding is essentially connected with sadness and despondency, and as this is not the case, the latter term is much less exceptionable, although not always strictly applicable, for the reason just assigned. The expression, therefore, which I have made use of at the commencement of this section is more applicable to the different states of this species of derangement, than any single word that can be employed. Although the illusions which possess the minds of persons partially insane are as varied as the operations of the intellect, yet they very frequently are productive of either happiness or distress to the patient. Hence they admit of being divided into those which are pleasurable or exciting, and those which are gloomy or depressing, — a division, indeed, which has been adopted by RUSH and ESQUIROL. Still there are some predominant ideas, which do not necessarily produce either happiness or misery, but which may be contingently associated with either, or with each alternately. Indeed, many persons become insane upon some metaphysical or abstract subject, on which they talk absurdly, but without any disposition to grief or to elevation of mind. It should also be remarked, that M. ESQUIROL has comprised under monomania those states of moral disorder already noticed, and which have been excluded by Dr. PRICHARD, under the belief that they are unconnected with any illusion or hallucination. But, as I have already contended, the judgment is more or less impaired in these states of moral disorder, although not to such an extent, or in such a way, as to give rise to a precise morbid perception, or perversion of the understanding; and self-control is remarkably weakened.

97. The forms of partial insanity of the understanding have been distributed into many orders or kinds. The subdivisions would be endless, if it extended to as many different kinds as there are modes or varieties of hallucination; at most a division can be founded upon the prevailing passions or emotions, which give origin, and impart their peculiar character, to the disorder; but even this would be too extended. It might, therefore, be sufficient to arrange them into —1st, Those characterised by exaltation or excitement; and, 2dly, Those evincing more or less depression. This arrangement, however, would exclude more than one of the varieties of mental disorder which fall under the present head, or of those hallucinations which are not necessarily connected with either exaltation or despondency, and which yet may be attended by either. It will be preferable, therefore, after having taken a general view of this species of insanity, to notice more particularly the chief forms which it most frequently assumes.

98. *a*. GENERAL VIEW OF PARTIAL INSANITY. — The remark already made (§ 68.) as to moral insanity, is also applicable, and even more so, to partial disorder of the understanding; and this is, that the mind is not perfectly sound on subjects unconnected with the particular impression by which it is possessed and more prominently disordered. There are certainly cases in which the understanding seems quite rational on all topics, excepting those connected with its illusion or hallucination; but, even in these, it will be found, on closer observation, more or less weakened or impaired, owing to deficient powers of attention and comparison. The individual affected is certainly, in ordinary circumstances, calm, and devoid of those signs of perturbation and constant excitement characterising mania, or raving madness. But it will be found, that his habits and disposition have been long more or less changed; that he has presented a greater or less degree of moral insanity; that his powers of application and attention have been weakened for some time; and that an erroneous belief or illusion has gradually arisen in the course of these disorders. Very frequently a settled or habitual despondency, or melancholy, or moroseness of temper, or even a sullen misanthropy, has existed, has slowly increased, and has disordered and perverted his feelings and affections. Ultimately some delusion supervenes, which may at first be fugitive, but which afterwards becomes more fixed and constant.

99. *a*. Dr. HOLLAND very justly remarks, respecting the commencement of the slighter forms of partial disorder of the understanding, that many persons have felt, at one time or other (oftenest, perhaps, during the "severa silentia noctis"), some dominant idea or feeling to possess the fancy, retaining its hold with a sort of malignant power, despite all efforts to shake it off; and, by degrees, distorting the subject, especially if it be a painful one, into a thousand false and alarming forms. If this train of thought be interrupted, and time, society, and other objects, come in between, the mind is conscious of passing, as out of a bad dream which for a while had overshadowed it. But let there be a cause for the continuance of this state, and we have an approach to monomania in some of its various shapes; nothing apparently wanting but the intensity, which is often so singularly testified in these cases by the actions induced, and by the long duration of the delusion. PINEL mentions instances where the same single insane impression continued without change for twenty or thirty years.

100. The illusion which torments the monomaniac is generally something bearing a near relation to his former habits of business, or to the usual occupation of his thoughts. In fact, the long persistence of the mind in one idea or feeling, not duly broken in upon, or blended with others, is, as Dr. HOLLAND well remarks, a state always leading towards aberration. Indeed, the common, and often the only, evidence of insanity, especially in its earlier stages, is that drawn from the dominance of a single impression, faulty, perhaps, only in the absence of those which should modify and correct it. It may be alleged, that this reasoning tends to remove all distinction betwixt the sound and unsound mind, and to reflect madness back, as it were, upon the healthy and natural state of the faculties of man. But this is not truly so. The extremes are widely apart, and are readily recognised. It is only in the slighter states of divergence, where mental health is lapsing into disorder, that marks of practical

distinction may be difficult, or misunderstood. The existence of more doubtful cases, graduating between reason and insanity, is but a part of that law of continuity, which pervades both the moral and the physical world; and which, although furnishing difficulty to the legal consideration of insanity, yet should present but little to the adoption of appropriate moral and medical treatment.

101. It is often difficult to account for the occurrence of the hallucination disordering the understanding. But, as just observed, the illusion entertained is generally connected with the former habits, business, and opinions of the patient. Dr. PRICHARD remarks, that an individual of a melancholic temperament, long influenced by circumstances impairing his health and calling into play the morbid tendencies of his constitution, sustains some unexpected misfortune, or experiences great anxiety, becomes despondent, and broods over his feelings, till the prospects of life appear to him dark and distressing. His inclinations now are so altered, that no motive can rouse him to exertion; his gloom and despondency increase; his imagination fixes upon some particular circumstance of a distressing nature, and this becomes afterwards the focus round which the feelings which harass him concentrate themselves. This circumstance is often some real, occasionally some trifling, act of delinquency, for which the patient expresses the strongest, and perhaps disproportionate, self-condemnation. In other instances, an unusual phantom suggests itself, in harmony with the prevalent tone of the feelings; and this at first haunts the mind as possible, and is at length admitted as reality. Some individuals begin by indulging morose or malignant feelings to their acquaintance; and, by magnifying in imagination every trifling neglect into a grievous contumely, they fancy at length that they find, in some casual occurrence, glaring proofs of premeditated designs to ruin them and expose them to the contempt of society. The disease in these cases has its real commencement long before the period when the particular delusion, which is only an accessory symptom, is discovered, and even before it became impressed on the imagination.

102. *β*. An undue indulgence in a single train of thought of any kind, particularly when involving any moral emotion, may lead to partial insanity, especially when the individual is physically disordered, or is out of health — when his digestive, assimilating, and excreting functions are deranged, and his nervous energies are weakened; and this is the more likely to occur, if his intellectual and moral powers have been imperfectly or improperly cultivated in early life. In these cases, the insanity is gradually developed, or in a similar manner to that now described: in some it is the consequence of excessive devotion to a particular department of abstruse investigation — of exertion beyond the natural energy of the mind in one particular direction, and to the exclusion of countervailing healthful occupations of the intellectual and moral faculties, and of requisite relaxation of mind; in others, it gradually arises out of the habitual indulgence of some moral emotion or sentiment, or of some more violent passion, intellectual energy becoming impaired, and at length more obviously disordered. In many instances of this kind, as well as of the preceding, the insane delusion is occasioned chiefly by fears, anxieties, expectations, and excitements, of either a religious, a political, or a domestic nature, or even by the terrors produced in weak and susceptible minds by the vehement language and denunciations of popular and other preachers. The following case adduced by Dr. PRICHARD illustrates the connection of the hallucination with previous occupations, and with the moral influences to which his mind was subjected. A young man, whose father was frequently employed in criminal prosecutions, had assiduously attended the sermons of a preacher noted for the vehemence of his exhortations, and had devoted himself, to the neglect of sleep and bodily exercise, to studies, for which he was unprepared. He became depressed in spirits, and disordered both in mind and in body. The morbid feelings which afflicted him at length conjured up an imaginary cause for themselves, that soon became indelibly impressed on his belief. He fancied himself suspected of some horrible crime, for which a process had commenced against him; and, whenever the door of his room was opened, he supposed that officers of justice were coming to apprehend him.

103. It is unnecessary to adduce instances in proof of the position already stated, that the erroneous belief or delusion, constituting partial disorder of the understanding, is generally, or at least frequently, consequent upon, and afterwards associated with, previously existing moral insanity. Whether this connection exists so universally as Dr. PRICHARD believes, I will not assert; but it doubtless may be traced in the great majority of cases. It will further appear from what I have next to adduce, that the illusion is generally some notion as to the powers, property, or destination of the person affected, engrafted upon his habitual state of desire or aversion, passion or sentiment — or an erroneous idea or belief arising out of morbid sensations, which the imagination, influenced by predominant feelings, emotions, passions, or trains of thought, converts into diversified shapes; and that the illusion consequently assumes a character and form, more or less obviously moulded by such feelings and trains of thought.

104. *b*. HYPOCHONDRIACAL MONOMANIA. — *When the fears, apprehensions, and despondency of an individual are concentrated on his bodily feelings, relate to some disorder by which he is affected, and which he exaggerates, and are connected with an erroneous belief, or hallucination*, a state of disorder exists, which may be aptly termed *hypochondriacal monomania, or hypochondriacal disorder of the understanding*. The mental affection here gradually supervenes in the course of the bodily disorder. — The *first stage* of the malady is *hypochondriasis*, and does not, as I have contended (see the article, § 19.), amount to insanity, until the hallucination is manifested. It is true, that it is on the verge of insanity, — that it is closely allied to it, — and that it may be viewed, in its more fully developed states, as a variety of moral insanity; but still, until an erroneous belief is entertained, the mere exaggeration of bodily ailments, and the apprehensions, despondency, and concentration of the attention towards them, do not constitute, especially in the eye of the law, a true form of mental derangement. In the great majority of

instances, the hypochondriacal affection does not pass into, or occasion, an insane delusion; but when this change has taken place, and when a man fancies that his head is too large to enter in at the door, that his legs are made of clay, or that he has a fish or a demon in his stomach, the nature of the disease is different, and in no respect doubtful.

105. A flatulent hypochondriac may ultimately suppose that a living creature or a demon, according as he may be influenced by religious or superstitious ideas, is actually lodged in his abdomen. Dr. Jacobi (*Samml. f. d. Werk. der Gemüthekrankheiten.* Elberj. 1822, p. 21.) mentions the case of a man, quiet and rational on other topics, who entertained the notion that there was a person concealed in his belly, with whom he held conversations. He often perceived the absurdity of this idea, and grieved in acknowledging and reflecting that he was under the influence of it, but yet could never get rid of it. An attempt was made to cure this man by applying a large blister on his abdomen, and, when it was dressed, and the vesicated skin snipped, by throwing from behind him a dressed-up figure, as if just extracted from his body. The patient at first believed in the success of the performance, and was joyful in the full persuasion that he was cured; but some morbid sensation about the bowels, which he had associated with the insane impression, being again experienced, he took up the idea that another person similar to the first was still left within him.

106. *c.* Melancholic Monomania — *Melancholia* of authors — *Lypémanie* of Esquirol — *Tristimania* of Rush — *Melancholia with delirium* of Pinel — *is characterised by sadness and despondency, the mind being given up to fears and anticipations of evil, to an erroneous belief or impression, concerning one subject, or a particular series of subjects.* — Authors since Hippocrates have applied the term melancholia to delusions characterised by sadness and despondency; and this form of insanity was, according to Galen, so denominated, because all the sad or desponding moral affections depended upon a depravation of bile, which had become black, and obscured and disordered the animal spirits. Cælius Aurelianus and most of the ancient writers did not distinguish between melancholia and hypochondriasis; and even the authors of the 15th, 16th, and 17th centuries continued to confound them, although various relations between melancholia and other affections of the mind were distinctly pointed out by them. M. de Héréda and Forestus first noticed the connection of gloomy ideas and despondency with a partial delirium, or delusion, in this malady; and Sennert considered that the insane delusion was consequent upon despondency. Hoffmann and Boerhaave marked the relation between melancholia and mania, and the frequent origin of the latter in the former, — thus regarding melancholia as a slighter grade or earlier stage of mania. Sauvages defined melancholia to be a partial or exclusive delirium, without furor or excitement, associated with a chronic disease. Cullen was among the first who took a correct view of this malady, and who carefully distinguished it from hypochondriasis; but it is chiefly to Pinel, Esquirol, and Guislain, that we are indebted for accurate ideas as to its nature and relations.

107. *a.* Most writers have been more particular in their descriptions of the fully developed state of melancholia, than in pointing out the origin and rise of the malady, the importance of which is by no means small; and have overlooked the commencement of it in the moral disorder already noticed. M. Guislain and Dr. Prichard have, however, remarked the absence of delusion in the more simple and early forms of the complaint. M. Guislain observes, that there are melancholics without delirium or hallucination, as well as maniacs without any remarkable disorder of the intelligence, and these exhibit the most simple form of the distemper. Such persons are sad, depressed, despondent, &c.; but evince no remarkable aberration of the imagination, of the judgment, or of the intelligence. In this stage or state of disorder there exists only a form of moral derangement, which may proceed no further. But when erroneous notions or delusions, or a disposition to entertain an idea of suicide, or attempts to commit it, are manifested; or when any unusual or irrational determination is shown; then the disorder is no longer simple, but is fully developed and established, and actively influences the will.

108. In this state the patient is quite cognisant of what takes place around him; he appreciates more or less his situation, and recognises his friends and enemies; but fear, despair, or despondency, govern him — he is absorbed by the painful sentiment. Overwhelmed by it, prostrated, lying on his bed, or sitting with clasped hands, his head bent forwards, his eyes obliquely fixed on their object, he presents the very image of sadness. His voice is low; his expressions and acts are slow, prudent, and distrustful; he answers only in monosyllables; seeks solitude, and is reserved. His countenance is pale or sallow; his features are altered; his brow more furrowed; and he appears older than he is. He often complains of a sense of weight in his head, and sometimes of a void or of a feeling of emptiness in his cranium, occasionally with uneasy sensations or pains in the scalp. His repose is unsound — his senses only being asleep, while his mind is awake; and he complains of not enjoying an hour of sound repose; but occasionally he is somnolent. He is kept awake by his fears, jealousy, or illusions; and when he dozes, he is terrified by phantoms and frightful dreams. One, after having passed a good night, is more depressed and unquiet. Another believes that he will not get over the day, and yet feels better as the night approaches; and a third has his inquietude increased at night, dreading the solitude, the obscurity, the sleeplessness, the frightful dreams and phantoms attending every attempt to get rest.

109. Some refuse for several days all kinds of nourishment, restrained by illusions or hallucinations which increase their chimerical fears. Some dread poison, dishonour, &c.; and others abstain from food, in order to escape from a wretched existence, or to do penance for a supposed crime. The sensibility of some is acute, and the slightest occurrences produce the most vivid impressions. Heat, cold, rain, wind, light, noise, and all physical agents affect them inordinately. If there be the slightest cause of fear, they are terrified; if there be the least cause of regret, they are in despair; if they suffer the smallest reverse or disappointment, they be-

lieve themselves ruined. Their nervous system is morbidly susceptible, and their moral emotions, especially those of a gloomy kind, are remarkably exaggerated. They are physically and morally susceptible; and yet their sensibility is concentrated upon one object, or train of ideas. So complete is the concentration of their feelings, that they are almost inaccessible to impressions unconnected with the subject of their melancholy; a moral abyss separates them from all objects and sentiments that present no relation to their fears or delusions.

110. Anxieties and fears respecting any matter, and all the depressing passions, particularly when long indulged, or frequently reiterated, sway the intellect and judgment, and originate thoughts the most opposed to the dictates of common sense. These may ultimately pass into false perceptions and hallucinations, which will further increase the unjust inferences, the morbid belief, the unfounded fears, and the terrors already entertained. Fear, in all its forms, whether proceeding from a real or an imagined cause, exercises a dominant influence on the melancholic. A person whose fears have been excited by denunciations against religion, becomes, under the influence of these fears, anxious and depressed; his sentiments and power of attention are concentrated upon the object of his insanity; his fears exaggerate their causes, as well as the consequences which these causes may produce; and at length delusions are generated and entertained, influencing not only his thoughts, but also his actions. The victim of fanaticism or superstition may thus ultimately believe himself to be pursued by the vengeance of Heaven; or he may become the prey of anxieties, as to his state, so intolerable as to lead him to prefer death to incertitude. He who has offended the laws, continually apprehends the officers of justice; and, at last, believes himself in their power. Another, who has long dreaded the wickedness of man, ultimately believes that some one threatens his fortune, his honour, or his life; the least noise, sign, or doubtful word, exciting and confirming his fears or his belief. Some are afraid of every thing, and are subject to perpetual anxiety, or are terrified by a vague sentiment, without motive or object. Their expressions, attitudes, actions, and discourse, express extreme fear, which they cannot overcome, and which they cannot explain, or account for.

111. The delusion of the melancholic derives its character from the moral affection which preoccupied the mind on the appearance of the malady. A merchant has experienced losses of little moment, and he believes himself ruined, notwithstanding demonstration to the contrary; two brothers have had a dispute, and one becomes persuaded that the other has an intention to murder him, to obtain his property. Frequently, some one of the moral sentiments of the melancholic is so remarkably exaggerated, as to predominate over every other consideration, and to give rise to acts of despair. Many of the murders committed during this malady are the result of this morbid state of feeling. A mother abandoned by her husband attempts to destroy her children, to prevent a similar misfortune; and a religious enthusiast kills his infants, to send them to heaven before their minds are corrupted.

112. Some melancholic persons are conscious of the absurdity and the falsity of the fears by which they are tormented. They reason respecting them, and even are distressed at being the victims of their apprehensions; but still they continue a prey to them, and they find it impossible to think or act otherwise than under this dominion. An insurmountable power governs their reason, and they believe that the Almighty, or some demon, or fate, or some other power, influences them. The will of the hypochondriac is inflexible. No consideration or sentiment can overcome his alarms and errors, or his aversions.

113. *β*. The *physical symptoms* of melancholia vary much in different persons, and even in the same person in different periods of the disease. The patient sometimes has a sense of constriction in the chest, and places his hand over the heart, complaining of anxiety and oppression, or of pain in that organ. The pulse is more frequently slow, than natural or accelerated. The tongue is often loaded, the appetite is impaired, the bowels costive, and the whole series of digestive functions more or less deranged. The urine is often pale and abundant.

114. *γ*. The *Diagnosis* of melancholia from hypochondriasis becomes a matter of some importance, seeing that they have been confounded by the older writers, and that the one may be mistaken for the other. Melancholia is more commonly hereditary than hypochondriasis, depending upon the melancholic temperament, which predisposes to the operation of the exciting causes, especially errors in education, and other influences acting directly on the brain, the sensibility, and the understanding. The causes which produce it are more generally moral; whilst hypochondriasis more commonly proceeds from causes which are physical, and which modify the functions of the stomach and other digestive organs. In melancholia there is a fixed delusion or insane idea, which is entertained with sadness and despondency, and a vicious association of ideas. In hypochondriasis, on the contrary, there is no insane delusion, until the disease passes into melancholia; but the patient exaggerates his sufferings — his mind is continually occupied with his ailments, which he believes to threaten his life — and he is continually subject to dyspepsia and other disorders of the digestive functions. — See article HYPOCHONDRIASIS (§ 19.).

115. *δ*. The *Causes* of this species of insanity are — the melancholic temperament, hereditary conformation or constitution, moral susceptibility, and increased sensibility; sudden shocks, reverses, disappointments, anxiety of mind, and all the depressing sentiments; frights, terror, fear; losses of fortune or of friends and connections; political reverses, and changes, and revolutions; fanaticism, superstition, and unsound views of religion; wounded self-love, humiliating circumstances or occurrences; masturbation, and whatever causes physical and moral exhaustion; and injuries of the head. — The *pathological* causes are chiefly — the suppression of accustomed discharges, protracted indigestion; and hypochondriasis, diseases of the heart, and of the digestive organs, obstructions of the liver and mesenteric glands, diseases of the uterus, &c. Most of these, however, are rather coincident disorders, than influential agents in the production of the mental affection.

116. M. ESQUIROL states, that of 482 cases of melancholia, the chief causes were—hereditary pre-

disposition, in 110; domestic unhappiness, in 60; reverses of fortune and distress, in 48; disappointed affection, in 42; the critical period of life, in 40; the puerperal state, in 35; venereal excesses, in 30; suppressed menstruation, in 25; intemperance in wine, in 19; frights, in 19; anger, in 18; wounded self-love, in 12; injuries of the head, in 10; jealousy, in 8; and masturbation, in 6. It is obvious, however, that this is only an approximation to accuracy, as, in many cases, several causes have concurred in producing the disease.

117. ε. The *course* of melancholia is usually continued, but is sometimes remittent, or even intermittent, or recurrent. It has even been observed to have been periodic. — Its *duration* is most variable. When it terminates in health, the change generally takes place between the third and the thirteenth months, — six months being about the average duration of these cases. Although there is so little moral reaction in this species of insanity, yet it is amongst those from which recovery most frequently takes place. A favourable change has been observed to follow the occurrence of a natural evacuation, especially when that has been suppressed, as the menstrual and hæmorrhoidal discharges, &c. It has also disappeared after the breaking out of boils and cutaneous diseases. The occurrence of hæmoptysis, of tubercular consumption, and of asthma, has sometimes been observed to dissipate an attack of melancholia; but the patient has died of the consecutive malady.

118. On the other hand, various organic lesions often appear in the course of melancholia, and are to be viewed rather as being favoured by it, than as accidental occurrences. Certain of them, indeed, have been considered as concerned in the production of the mental disorder; but it is much more probable, that the physical and moral changes are the results of the state of organic nervous influence, although the physical may augment the moral, and *vice versâ*, — the one acting and reacting on the other.

119. ζ. The *visceral diseases* most commonly observed in the course of melancholia, or in fatal cases of it, are tubercular and other organic lesions of the lungs, chronic pleuritis, enlargements and engorgements of the liver, alterations of the heart and spleen, and various displacements of the colon, particularly the descent of the transverse arch. This last change was first insisted on by M. Esquirol; and has been observed in melancholia by Bergman, Wichmann, Hesselbach, Guislain, Müller, Annesley, and myself. The transverse arch is sometimes displaced obliquely, so that its left flexure is carried downwards behind the pubis, and it occasionally descends perpendicularly, in a loop or duplicature, as far as the pelvic cavity. Displacements of this viscus are observed also in other forms of insanity, but not so frequently as in melancholia. M. Esquirol considers that organic lesions of the brain are not frequent in this species of the disease; the number of cases in which changes were observed by him in this part being much smaller than observed by M. Foville and others, who have more justly appreciated the minute alterations which take place in it during mental disorders. M. Esquirol confirms the remark of Lorry and Mead, that tubercular phthisis is the most frequent cause of death in melancholia, and subjoins the following enumeration of the organic lesions found in 168 cases: — *Within the cranium* — thickening of the membranes, 2; organic alterations of the substance of the brain, 4; ossific deposits in the falx, 3; effusions of blood in the brain, 5. *In the chest* — organic lesions of the lungs, 65; disease of the heart, 11; effusion into the thoracic cavities, 6. *In the abdomen* — displacement of the colon, 33; adhesions and suppurations of the peritoneum, 5; ulceration in the stomach or pylorus, 6; ulceration in the intestines and rectum, 7; intestinal worms, 5; tænia, 1; organic lesion of the liver, 2; biliary concretions, 7; ulceration in the uterus, 6.

120. η. Melancholic monomania may *pass into*, or become *associated with*, some one of the other varieties of insanity, or even with more than one of them. It occasionally passes into mania, and even degenerates into dementia. In this state the patient retains the predominant ideas; but these are incoherent, without order, and do not harmonise with the actions; whilst previously the ideas were strong and fixed, and the determinations of the will were the immediate results of the characteristic delusion and trains of thought.

121. δ. Demonomania. — The Chaldeans, the Phœnicians, the Jews, and the Greeks believed that most diseases, particularly those of the brain and mind, proceeded from demons or evil spirits. Job was said to have been the victim of a demon; and Saul to have been under the influence of an evil spirit. Aristophanes termed the highest grade of madness, not *μανία*, but *κακοδαιμονία*. Herodotus was, however, nearer the truth, when he said that Cleomenes had become mad from intoxication among the Scythians, and not by the presence of a demon. M. Esquirol has, conformably with the original acceptation of the word, comprised the two varieties of partial insanity about to be noticed, under the appellation of *Demonomania*. The first of these varieties, or *Theomania*, is still of frequent occurrence; the second, or *Cacodemonia*, was common in ancient times and during the prevalence of popish superstition; and, indeed, still frequently occurs in countries where superstition lingers.

122. α. The *Theomaniac* is characterised by an enthusiastic belief in divine selection and acceptance, and in the future eternal damnation of all who do not think, as to religious matters, exactly as he does; by a belief of having received revelations from the Almighty, or of being inspired, or of holding communications with the Holy Spirit, or with angels or saints; or by a belief of having received a mission from Heaven to convert sinful men. Persons who have had their minds inordinately excited by preachers who are themselves thus affected, or who are noted for the vehemence of their language, and by the enthusiasm of their belief in the more alarming or exciting topics of religion; or those whose thoughts have been long or painfully directed, especially during nervous exhaustion and susceptibility, to these topics, and to the punishments of a future state, and have become impressed by exaggerated ideas of their own wickedness; not infrequently become melancholic, and after a time theomaniac. But, whilst this latter state of mental disorder may thus appear consecutively in some, it may occur primarily, from the same moral causes, in others. In the former cases, it is a state of morbid mental reac-

tion consequent upon the previous depression, and belief of condemnation; in the latter, it is a state of primary mental excitement, connected with more or less delusion. The instances of religious excitement furnished by the "revivals," the camp meetings, and field preachings in America and Scotland, the modern "gift of tongues" in this metropolis, are all forms of this kind of partial insanity; which, however, is sometimes of temporary continuance only, especially in hysterical and excitable females; but which often passes into more furious mania, or confirmed insanity. The frequency of this form of mental disorder in females, and other circumstances belonging to its history in this sex, show its occasional connection with hysteria; and that at least the hysterical state favours its occurrence.

123. *β. Cacodemonia.*—Newton remarks, that when men abandoned the worship of the true God, the stars became the first objects of their idolatry, as most striking to the senses; and were supposed to exercise a continued and active influence on the mind. Melancholy was then thought to depend upon the course of the planets; and the frequent periodicity of the disorder confirmed the belief. Hence the word *μηνη*, luna, furnished the appellations mania, lunaticus, lunacy, for this and other mental disorders. The doctrine of spirits taught by Socrates, Plato, and even by still more ancient philosophers, having become associated with Christianity, the influence of these spirits upon the human body became an article of general belief, and was implicitly received, until the Reformation, and the mental freedom to which it led, dispelled the mists of superstition. The dread of yielding to the instigations of the devil, and of being in the power of demons, led to the institution of exorcisms, and to ceremonies in the more primitive church, to deliver those who were believed to be thus possessed. These ceremonies tended to cherish the idea as to the influence of evil spirits; and was, indeed, with various concomitant circumstances, the chief cause of the continued belief in this source of mental disorder. With the extension of popish superstition, the numbers of demonomaniacs increased; and, in many of the larger cities of Europe, stated feasts and ceremonies were established for their cure. The pomp and solemnity observed on these occasions, and the crowds assembled, struck the imaginations of those affected, and contributed to the cure of a few of them. In these times, demonomania assumed a variety of forms,—and the most common and the most recent were those of sorcery and witchcraft. As long as both church and state prosecuted and cruelly punished those objects of self-delusion and of popular belief, the community were firmly persuaded of the reality of demonomaniacal possession; but as soon as governments ceased to punish these extravagancies, the chimerical fears which affected the populace, and by which the minds of the weak, of the melancholic, or of the hysterical were tortured, gradually subsided, and ceased to produce their wonted effects, and cases of this form of derangement were rarely observed. The progress, also, of education and of knowledge dissipated these errors, which led to, and nurtured, a belief in the influence of demons; yet still, in popish countries, some monomaniacs believe themselves in the power of demons, and furnish instances which may serve to illustrate, or to explain, the psychological extravagancies which disgraced governments and religion for so many centuries. The delusions arising out of ignorance, improper education, and superstition, gave rise, in those days, not only to the most humiliating errors of the understanding, but also to the most cruel exhibitions and actions of which human nature was capable. The history of mental delusions arising out of the superstitions, the wild doctrines, and the fanatical extravagancies which disgraced Europe for so many ages, furnishes innumerable proofs, not merely of the narrow limits of the human understanding in those times, but also of the degraded state of the passions and moral sentiments. How frequent and how horrible were the instances which then daily occurred, not only of the delusions of ignorance and superstition, but likewise of the lowest depravation of moral feeling! A reign of superstitious terror continued to exert its baneful influence on the human mind, blighting the intellectual powers, and withering the most generous and ennobling of the moral emotions.

124. In the present day, although the instances of monomania arising from a belief in the power of demons, or evil spirits, are rare, those which proceed from other causes of terror — especially from the fears of future damnation, as inculcated by fanatics and enthusiasts, and from the dread of imprisonment or of civil punishment—are as numerous as ever, — each case presenting characters derived from the principal cause of disorder. In modern times, M. Esquirol remarks,—and especially during the civil commotions in France, in the end of the last, and commencement of the present, centuries, — monomaniacs express as much dread of the tribunals of justice, as they formerly entertained of the influence of demons and of evil spirits. It is always fear, dread, and anxiety, which affect these unfortunate creatures, and cause the disorder which possesses them.

125. *c.* Misanthropic Monomania is sometimes met with, particularly in persons of a melancholic temperament, who have become hypochondriacal, or who have experienced disappointments in their affections and friendships, or who have been unfortunate in their attachments and well-founded hopes. In these persons, and even in others where the origin of the affection is less manifest, dejection of spirits is associated with malevolent feelings; and the resulting effects are, a distrust of every one, and a belief in machinations and persecutions intended for their ruin. They are in a state of continued misery; they believe themselves objects of universal hatred and detestation. They not only conceive plots of all kinds being formed against them, but also consider their dearest friends to be their most implacable enemies. They suspect poison in their food or drink; and their imaginations convert every act or every expression into designs to injure or to insult them.

126. *f. Excess of self-love* is an ingredient in every modification of monomania; but when exaggerated ideas connected with personal advantages or mental accomplishments are entertained, —when self-love, in the more common forms of vanity or of pride, is inordinately indulged,— either the mind becomes disordered from the repeated or continued contemplation, or the mental disorder is coloured by this circumstance when produced by other causes. Dr. Prichard observes, that ex-

cessive self-love, combined with an elated and sanguine disposition, instead of depressed spirits and a morose temper, produces cheerful illusions, which always maintain their relation to the person of the lunatic. A monomaniac fancies himself a king, the pope, a favourite of Heaven. This, however, does not constitute a single delusion, leaving the mind perfectly sane upon other points; for the same individual generally magnifies himself in other respects. Nor does the gay and cheerful state of monomania always result from this association of excessive self-love with the sanguine disposition, as supposed by Dr. PRICHARD; but rather from a vitious education, and from the excessive indulgence of the emotions of vanity and pride, especially in early life, in connection with various concurrent causes acting upon the nervous system of susceptible, weak, and nervous persons.

127. *g.* The preceding comprises all necessary to be stated in order to recognise the more simple states of partial disorder of the understanding. But, as these states are often consequent upon moral disorder, and occasionally are associated with it from the commencement, the physician should be prepared to meet with, in practice, numerous instances of *the association or complication of these forms of derangement.* To describe the almost innumerable modes in which each of the several forms of moral insanity may be complicated or associated with either of the varieties of partial disorder of the understanding, would be endless; and even to adduce instances illustrative of some of the more striking states of this complication, would be far beyond my limits, and be attended by few advantages. The works of GUISLAIN, HEINROTH, PRICHARD, and ESQUIROL furnish sufficient examples of this association; and to these I refer the reader. Besides, no one can possibly mistake cases of this description, when they come before him in practice, nor misapply the means, moral or medical, which they require for their treatment.

128. ii. GENERAL INSANITY.—In general insanity, not only are the *moral emotions* and the *intellectual faculties* weakened or deranged, but all the *instinctive desires* and *feelings* (see note, § 66.) are also disordered. The ideas are in a state of confusion, and perpetual and general disturbance, and none of the powers or manifestations of mind can be exercised even for the shortest period. General insanity presents three principal species, usually denominated *Mania*, or raving madness; *Dementia*, or incoherent insanity and mental imbecility; and *Fatuity*, or annihilation of the mental faculties. To each of these I proceed to direct attention.

129. *A.* MANIA, or *Madness — Hyperphrénie*, of GUISLAIN — *Raving Madness — is characterised by a disordered association of ideas, which are reproduced without connection and with extreme rapidity, by remarkable derangement of the understanding or judgment, by alienation of the affections, by the violence of the will or volition, and frequently by false sensations, illusions, or hallucinations.* — It is either a chronic disease, or liable to lapse from an acute into the chronic state; is commonly unattended by general fever, although the pulse is usually more or less accelerated, especially at an early stage; and it chiefly consists of *perturbation* and *exaltation of the sensibility; of disturbance of the instinctive, the intellectual,* and *the moral manifestations of mind;* and of *excitement of volition.*

130. *a.* The *acute form of mania* presents itself in different grades of intensity; the *mildest* of which has been denominated by GUISLAIN, *Tranquil Mania*, and may be named *sub-acute mania;* the most violent, as described by CHIARUGGI and others, may be called *hyper-acute mania.* Either state, however, may pass into the other; and both may commence more or less suddenly, and reach their acme with great rapidity. Generally, however, *premonitory symptoms*, manifestly indicating very serious vascular disorder in the brain, have existed for some time before the mind becomes evidently deranged. In the case of an eminent writer on medicine, who died some years since, marked indications of vascular excitement in the brain were evident to me more than a twelvemonth before mania burst forth. Almost always for some days, often for some weeks, and even for months, before the disease is established, occasional fits of excitement and perturbation, disturbing for a time the judgment, are experienced. The patient is, during this time, or at various periods, in a state of agitation, of feverishness, and of uneasiness. He is restless; morbidly active; his imagination is lively; he is full of projects, often trifling or absurd; and he enters upon pursuits with energy, but relinquishes them quickly and without sufficient reason. His head is generally hot, his feet cold; his sleep is short, broken, and disturbed; and he either lies awake, ruminating on various speculations; or gets up, paces the room, or attempts to occupy himself, but each successive attempt is soon relinquished, in a state of perturbation, or of quiet distraction. During this period, some experience fits of painful terror, or of agitation, and not only pass sleepless nights, but by day are in a constant state of uneasiness and restlessness, or of action leading to the performance of little or nothing. Others are disquiet and depressed, and are impressed by a feeling of an impending calamity, or by a dread of losing their reason. In some, the appetite is voracious; but the stomach is readily disordered, and intemperance is followed by severe affection of this organ. In others, the appetite is deficient or capricious. The bowels are often torpid. At this period, a desire of intoxicating liquors, and intemperance in the use of them, are manifested suddenly, although previously disliked.

131. At length reason is overturned. The individual scarcely knows what he says; repeats his words often, or talks nonsense, or is unable to complete his sentences, or suddenly breaks off in the middle of them. He utters confused expressions, in a rapid or impetuous manner; or he makes ineffectual efforts to collect and to express his thoughts. He appears to those about him in a state resembling intoxication. He laughs, cries, is irritable, is prone to anger on the least opposition, and is most obstinate, self-willed, and capricious. This morbid state of mind may continue for some time, — particularly when humoured by friends,— without exciting much alarm, or leading them to adopt measures of restraint. At length, on some attempt being made to interfere with, or to oppose, his absurd pursuits, he breaks out into the wildest violence, and even attempts acts destructive of, or injurious to, others or himself, and requiring the most strict coercion.

132. This state may exist without any false perception, or delusion. Very frequently, however, as soon as violence is manifested, some illusion or hallucination, or absurd impression as to his own person or powers, or his relation to others, appears; but it is seldom permanent, as in monomania; it is soon forgotten, or gives way to some other phantom.

133. *a.* In the *milder*, or *sub-acute cases*, the disease may proceed without much violence, unless the patient be greatly excited; but his emotions are capricious, warm, and enthusiastic, and his ideas are confused, inconsistent, or unconnected. He seems half drunk, and like one who endeavours to collect his thoughts and to express them connectedly, but fails in the attempt. His temper is irritable; he is self-willed; his habits, feelings, and affections are changed; he is incapable of any exertion, of attention, or of thought; is in a constant state of uneasiness and of restless action, without being capable of performing any thing; and is altered in countenance, expression, and general appearance.

134. *β.* In *severer*, or *more acute cases*, or as the disease increases in violence, all the phenomena are more developed. The malady may proceed for many days, or even weeks, before it reaches its highest pitch. During this period, the derangement varies somewhat according to the predominance of particular feelings or passions. Sometimes the patient is terrified and agitated; frequently he breaks out into the most violent expressions of rage and enmity against his relations or friends, or whoever may have been obliged to exert control over him, or restrain his mad proceedings, uttering bitter execrations, or threatening vengeance and condign punishment. His nearest and dearest relatives are now the objects of his most vehement displeasure. As the malady approaches its acme, his ideas become more and more disordered and unconnected. His thoughts and feelings are expressed with exclamations and ejaculations, with the utmost agitation of countenance and manner, and with the most violent and irregular gesticulation and action. He is so absorbed by his internal sensations and emotions, as to be almost unconscious of external objects and impressions. He seems deprived of all affection, of all ideas of right and wrong, of every feeling of shame, of every principle of probity and honour, and of all parental or filial affection. The advice, conversation, or even the presence, of near relatives, irritates or exasperates him. He utters the most blasphemous, the most filthy and indecent, language; and the most injurious, calumnious, scandalous, and unjust expressions, respecting his dearest friends. Many maniacs are disregardful of cleanliness and personal decency, and are most disgusting in their expressions and habits. They seem as if excited by an internal heat, enabling them to bear, often with complete impunity, the continued impression of great cold; and they sometimes even complain of it either in the head, or in the abdomen, or circulating in their veins. Hence their desire to go almost without clothes, or to expose their persons. They are occasionally deprived of sleep for many days, or even weeks, together. They generally become more or less emaciated, and the features haggard, wild, or maniacal. Their eyes are watery, suffused, red, prominent, brilliant, and fixed or vacant. Their motions are quick and threatening; and the expression of their countenances so changed, as often not to be recognised by their friends. All the functions are now disordered. The bowels are obstinately costive, especially early in the disease; but afterwards they are often irregular. The appetite is frequently lost for many days; but it is sometimes voracious. The tongue is furred or loaded; the skin cold and clammy, excepting on the head; and a frothy saliva, mixed with mucus, is often excreted.

135. *γ.* The *most acute states of mania* have been graphically described by Pinel and Chiaruggi. At the commencement of such cases, the patient is impetuous, audacious, menacing in his aspect, and shameless in his habits; his forehead is contracted; his eyebrows are drawn up; his hair bristled, and his breathing hurried. His evacuations are deficient; and his skin becomes dirty and sallow. His countenance begins to glow; his eyes become fiery and sparkling; his looks unfixed; his eyelids drawn widely open and closely shut by turns; his eyeballs prominent or protruding and injected; he is insensible of cold and hunger; and his sleep is lost, or it is very short and unquiet. As the disease proceeds, his loss of reason, violence, and anger are remarkably increased; he shrieks, roars, rages, abuses his dearest friends; destroys or breaks whatever comes in his way; tears his clothes to pieces; and is often disposed to go quite naked, or with his person exposed. Whoever touches him, is abused or struck by him. His ideas are strangely confused, and his mind is occupied by absurd prejudices or delusions. After a period of violence, stillness takes place for a short time; and when alone, he talks, gesticulates, and exclaims, as if he were wrangling with persons about him. When restrained, or confined, his countenance assumes a satanical or ferocious expression: he throws away, with imprecations and shrieks, the food presented to him, but is compelled by thirst to swallow fluids. After some days, hunger begins to be felt; and often the most disgusting things are taken greedily. Even the excrements, in some instances, are devoured; and the evacuations, which are usually dark and offensive, are smeared over the clothes, beds, or walls. Notwithstanding the patient's constant exertion, and prolonged want of sleep, his muscular strength seems to increase; his limbs acquire remarkable pliability and nimbleness, and the greatest feats of strength and agility are performed without exhaustion. However bold and menacing he may be, a strong threatening voice, a piercing and commanding look, and even the sight of the means of secure restraint, readily daunt him. After his violence has expended itself, he becomes still, or gloomy, and appears as if brooding over something; but he breaks out, often unexpectedly, into a new storm of rage and violence. At length a real cessation of violent paroxysms ensues: exhaustion, with unquiet sleep, disturbed by fearful dreams, takes place. The pulse becomes small, the general aspect squalid and meagre, and the countenance pallid and haggard. The patient is now obstinately silent, or sings and laughs in a strange manner, or chatters with incessant volubility; and at times seems as if lapsing into a state of fatuity; but these uncertain intervals are frequently interrupted by short fits of violence. Memory, how-

ever, continues without much impairment during the course of the disease, and the senses possess an unusual degree of acuteness and susceptibility.

136. Acute attacks of mania generally attain their highest intensity, or begin to decline, in about a month from their commencement. In many, however, intervals, or remissions merely, of the violent symptoms occur, about or soon after this time; and from such remissions may be dated the accession of the advanced or chronic stage of mania. When patients do not recover after a succession of attacks, either the powers of mind are exhausted to so low a grade, that the disease lapses into permanent fatuity, or the mental exhaustion continues as a period of calmness, after which an attack of violent madness recurs; or it passes into a state of melancholy, or of mental incoherency. As the maniacal attack becomes chronic and confirmed, so frequently does it assume either of these forms; but, in the more prolonged cases, sense and understanding are more and more completely abolished. During the more acute states of the disease, patients are rarely affected by any epidemic or contagious malady; and, according to several authors, dropsies, consumption, and various other chronic diseases have disappeared on the accession of violent madness. In many cases, however, the disappearance of these has been illusive, the maniacal affection merely *masking* the pectoral or other disease, which may have been in some degree interrupted in its course, but rarely removed, or even materially benefited.

137. *b. Chronic* or *protracted mania* is generally consequent upon either of the forms of *acute mania;* but it may follow any of the varieties of *partial insanity*, already described; or it may appear as the *primary affection*. This last, however, is the least frequent mode of its accession. It is, in many instances, merely a stage of transition between acute mania and dementia or incoherency, but a very protracted one in most cases, and of very uncertain duration. It often lasts for many years, and sometimes for the greatest part of life, and is the state of alienation presented by the great majority of the inmates of asylums. *Chronic mania* is characterised by marked impairment of the powers of attention, memory, comparison, combination, and, consequently, of judgment; and is a state of intellectual weakness, in which none of the operations of mind is performed with effect, often associated with some false perception or delusion. The individual is quite incapable of continued conversation, and of the duties of society: his conduct and actions are without consistency, steadiness, or rational object; and his thoughts are wandering and incoherent, He presents a state intermediate between either monomania or mania, and dementia or incoherency — a mental condition, combining many of the phenomena of these disorders. It is to this class of cases — to this form of mania — that the term lunacy is, perhaps, most applicable. Dr. PRICHARD remarks that many continue long to display the characters of mania; but, except during particular periods of renewed violence or agitation, to which most are subject, they become more tranquil than at the commencement of this complaint. They show signs of incipient dementia combined with morbid activity of body, in which the excitement characteristic of their disease exhausts itself in almost perpetual action. Lunatics of a different class fall into a state of calm reverie; their imagination, abandoned to itself, without the control of judgment, gives itself up to wanderings without end. Even in attempting to converse, or when their attention is excited by questions, they exhibit a strange mixture of reason and mistakes, both as to facts and inferences. Others — and these are the most numerous — are governed by some particular passion, mental habit, or delusion; the illusion having reference to their own persons, or to their relations to other individuals.

138. The illusions in this form of disorder are not, like those in monomania, cherished in the mind, and brooded over in silence, in solitude, or in gloomy reserve: they are more connected with the present objects of sense, and are for ever changing with the casual alterations of feeling or temper. In a great number of those who are threatened with general paralysis, or who are already attacked by it, M. CALMEIL has shown a peculiar form of delusion to exist. The patient is in a state of exaltation or of joyous delirium, fancying himself the owner of millions, of towns, empires, &c. He is intoxicated by the flattering belief, and joy manifests itself in his features and gestures. Illusions of this kind often precede the accession of paralysis for several months, and continue for some time afterwards; but they are gradually obliterated with the last traces of intelligence, as dementia becomes developed. In other instances, the joyous delusion assumes a form of maniacal delirium, with excessive agitation and anger; and continues with short intervals of quietude until death ensues, or until it terminates in dementia. In a great many protracted cases, the principal phenomena are referrible to some particular habit or active propensity, and are unconnected with any hallucination or false perception. Indeed, every variety of human pursuit occasionally becomes the subject, in relation to which especially chronic madness is exhibited; and the disorder is displayed, in many instances, rather in the mode of action and conduct, and in the general weakness, or abolition of certain powers of the mind, than in any hallucination or illusion.

139. *c.* The *course* of mania is *continued, remittent*, and *intermittent*. The *remissions* may be more or less distinct and regular. They often take place every second day. Whilst there are many maniacs who scarcely ever sleep, there are some who sleep tolerably well. The former are often more quiet during the day than in the night. Others, again, are quieter and more impressible in the morning and in the evening. *Intermittent* mania is sometimes regular, and sometimes irregular, in its accessions. According to ESQUIROL, it constitutes about one third of the number of maniacal cases. It may assume either the quotidian, the tertian, or the quartan type. Or the attacks may recur every eight days, or every month or three months, or six months, or even after longer intervals. They are frequently induced by moral or physical causes, of a manifest kind, as contrarieties, and disorders of the stomach or bowels. Females often experience an accession of mania about each menstrual period, or after each lying-in, or when they suckle, or after weaning. In some it returns every spring, or every summer. Intermissions are more frequent in mania, than in any other form of insanity.

140. *d.* Mania is sometimes *complicated* with

cutaneous diseases, very commonly with hysterical symptoms in females, and often with hypochondriasis in men. It is frequently associated with epilepsy, and still oftener with paralysis, and with other forms of insanity; this last circumstance is the chief cause of doubt and difficulty in the classification of mental disorders.

141. *e.* The *Duration* of the malady varies from two or three days to many months or years. In its more prolonged forms it generally consists in a number of accessions and remissions. It may alternate with phthisis, hypochondriasis, and melancholia; but the pulmonary disease is only suspended during the maniacal attack. It may *terminate*, also, in either of these; but most frequently in dementia, paralysis, or fatuity, or in either dementia or fatuity conjoined with palsy.

142. *f.* The *Diagnosis* is apparent from the description I have given of mania. The more or less general disorder of the mental powers, and the turbulence, violence, and agitation attending it, sufficiently distinguish it from melancholia, and other forms of partial insanity. In the latter, a few only of the affections, the passions, and the desires, or of the sensations, perceptions, or ideas, are deranged. In mania, all the powers concerned in forming the understanding, and in distinguishing between right and wrong, are overturned; and the ideas, feelings, passions, and impulses arising in the mind violently influence the will, they being no longer controlled by the powers of the understanding, nor guided by notions of propriety. The violence, perturbation, and rapid transition of passion, of impulse, and of action, are consequences of disordered excitement, expressed more or less generally upon the moral emotions, and of deprivation of the instinctive feelings and of the intellectual powers, as well those of consciousness as of intellection and reflection. The moral emotions or affections of mind being morbidly excited and uncontrolled by the restraining and guiding influence of feeling and intellect — of affection and judgment — the disordered impulses of the will, and the disposition to commit absurd acts, become strong and violent, especially when opposed, unless the opposition be manifestly above removal.

143. *g.* The *Prognosis* is more favourable in this form of insanity, than in any other, although the most violent and alarming in its symptoms. — *a.* A *favourable result* is often attended by some critical evacuation or change, and especially by discharges from the stomach or bowels; by bilious evacuations; by epistaxis, hæmorrhoids, menorrhagia, leucorrhœa; by ptyalism; by cutaneous eruptions, particularly boils, carbuncles, and erysipelas. As long as mania is simple, it is cured more frequently than any other mental disorder; and especially if there be no very apparent or strong predisposition to it. A first attack generally admits of cure, if it be not complicated with palsy or epilepsy. A second seizure is also often removed, if it remain uncomplicated. But recovery becomes very much more doubtful after the third attack. M. Esquirol states, that of 269 cases of mania that recovered, 132 were from first attacks, 77 from second, 32 from third, 18 from fourth, and 10 from a greater number of seizures. The duration of the disease, in cases of recovery, is much shorter than in other forms of insanity, recovery generally taking place within the first year. Of the above 269 cases, 27 recovered in the first month, 32 in the second, 18 in the third, 30 in the fourth, 24 in the fifth, 20 in the sixth, 20 in the seventh, 19 in the eighth, 12 in the ninth, 13 in the tenth, 23 in the eleventh and twelfth, 18 in the second year, and 13 after the second year. The greater number of recoveries took place in autumn and summer.

144. *β.* An *unfavourable issue* is to be anticipated, if mania has continued longer than two years, and if it be complicated with palsy, epilepsy, or any organic disease. It is certainly fatal in any of these complications, chiefly from the nature of the malady associated with it. Instances are very rare of simple mania terminating fatally. The most frequent maladies causing death in mania are typhoid, or adynamic fever with cerebral affection, general paralysis, pulmonary consumption, epileptic convulsions, and exhaustion of nervous power. M. Esquirol asserts, that no appreciable organic lesion is found in the brains of those who have been subjects of recent uncomplicated mania. But in this, as will be shown hereafter, he is opposed by MM. Foville, Calmeil, Bayle, Guislain, Haslam, Prichard, and others.

145. *h.* The *Causes* which produce mania more especially may be briefly enumerated. — *a.* The acute states of the disease take place most frequently in spring and summer, and chronic cases are often exasperated in those seasons, and in high ranges of temperature. The disease more frequently commences some time between the fifteenth and forty-fifth year, than at any other epoch of life; and it is only in robust persons that it appears later than the fifty-fifth or sixtieth year. When it occurs at an advanced period of life, it is very apt to pass quickly into dementia, or to become complicated with paralysis. It also is more common in males than females, and assumes a more acute or violent form in the former than in the latter. Sanguine, nervous, and irritable temperaments, plethoric and robust constitutions, and susceptible and ardent dispositions, are most predisposed to this species of insanity. Employments and professions have a less marked influence in causing it: yet it appears to be somewhat more frequent in merchants, speculators, military men, and artists, than in persons otherwise occupied.

146. *β.* The individual occasional causes of mania are numerous, and very rarely act singly, but generally in various combinations, in producing their effects. In many cases, there is not merely a concurrence of causes, but also a certain sequence in their operation, necessary to produce the disease. A fright occasions suppression of the catamenia, and this is followed by mania, which subsides upon the return of the uterine discharge. — *Moral* causes are more influential than physical causes. Disappointed affection, frights, jealousy, and domestic misery, affect women chiefly; whilst mental exertion, reverses of fortune, and wounded self-love, principally affect men. — Of *physical* causes, hereditary conformation is by far the most common, and it is almost equally so in both sexes. The next in frequency are parturition, suppression of the catamenia, and abuse of spirituous liquors. The following enumeration is according to the influence they exert, as estimated by M. Esquirol. *Moral causes.* — Domestic unhappiness, disappointed love, fright, reverses of fortune, want, humiliated or injured self-love, excessive mental

exertion, jealousy, and passion. *Physical causes.* — Hereditary disposition, parturition, disordered menstruation, the abuse of intoxicating liquors, venereal excesses, masturbation, the critical periods of life, injuries of the head, insolation, fevers, the suppression and disappearance of cutaneous eruptions and of accustomed discharges, the abuse of mercury, apoplexy, epilepsy, &c., hypochondriasis, and melancholia, have been also enumerated as causes, but they are, when observed, the early or premonitory stage of the malady. (See *General View of the Causes of* INSANITY.)

147. *B.* DEMENTIA — *Incoherency — Imbecility — Amentia,* SAUVAGES — *Incoherent Insanity,* PRICHARD — *Démence,* PINEL — *is a chronic form of insanity, characterised by impairment of the sensibility and of the will, by incoherence of the ideas, and by the loss of the powers of consciousness and of the understanding.* — A person thus mentally deranged is no longer able to perceive and apprehend matters correctly, to seize their relations, to compare them, or even to attend to them. He cannot comprise, in his mind, an exact idea, or even a tolerable notion, of any one subject or object; but is occupied unceasingly with unconnected, incoherent thoughts, and with emotions arising spontaneously, without association or aim. PINEL defines this state of mental disorder to be an incoherency of ideas, which have no relation to external objects; a turbulent and incoercible mobility; a rapid and instantaneous succession of ideas which seem to be developed in the mind, without any impression having been made upon the senses; a continual and ridiculous flux and reflux of chimerical ideas and notions, which destroy each other almost as soon as produced, without intermission and without connection; a similar incoherent but calm concurrence of the moral emotions, of the sentiments of joy, sadness, or anger, which arise and disappear spontaneously, without leaving any trace, and without evincing any correspondence with external impressions.

148. *a.* An imbecile or demented person is deprived of the power of adequately perceiving objects or circumstances, of seeing their relations, of comparing them, of preserving a complete recollection of them; whence results the impossibility of reasoning or reflecting on them. He is incapable of forming any opinion or judgment, because external objects make too feeble an impression; because the organs of transmission have lost a part of their energy, or because the brain itself has no longer sufficient power to receive and to retain the impression transmitted to it: hence the feebleness, obscurity, and incompleteness of the sensations and perceptions. Being unable to form a just idea of occurrences or objects, the demented person cannot compare them, or exercise abstraction or association of ideas; his mind has not energy enough to exert attention, or any mental operation necessary to the integrity of its functions. Hence the most incongruous ideas succeed each other, without dependence and without connection or order: hence he talks without being conscious of what he says; and he utters words and sentences without attaching to them any precise meaning. It seems as if unreal expressions were heard by him in his head, and as if he repeated them in obedience to some involuntary impulse, the result of former habits, or fortuitous associations with objects which strike his senses.

149. A loss of the powers of perception, of attention, and of suggestion or association of ideas, and the consequent defect, or entire loss of memory — of the powers of consciousness and of intellection (see note, § 66.), — are manifestly the earliest and fundamental changes constituting dementia, whether in its *primary*, or in its *consecutive forms* (§ 150, 151.). Hence the want of sequence or connection between the ideas, the intellectual imbecility, and the assemblage of phenomena, which I have stated this disorder to present. It must be obvious that, originating in the failure of those fundamental powers, dementia will *vary in grade,* with the amount of such failure; and that the resulting effects, manifested by the higher faculties and by the moral emotions, will also vary, not only in degree, but also in kind, according to previous habits, disposition, &c. — giving rise, at first, to *imbecility* or to *incoherence,* the two slighter grades of *dementia.*

150. Incoherency, imbecility or complete dementia, appears either *primarily,* from the operation of the predisposing and exciting causes upon the mind or constitution; or *consecutively* upon other disorders of the mind or brain, which, by their long duration, or their severity, affect the alliance of the former with the latter, and the intimate condition of structure of the brain more especially. When dementia occurs *primarily,* it is usually caused by whatever overwhelms the powers of the mind, or completely exhausts them, as inordinate mental exertion, vehement emotions, protracted and inordinate anxiety; and, as I shall have to point out hereafter, it may thus appear primarily, not only as simple incoherency, but also complicated with general paralysis or epilepsy.

151. Where dementia takes place *secondarily,* it is generally directly consequent upon protracted mania, or upon partial insanity, or upon apoplexy, severe phrenitis, epilepsy, palsy, irregular gout, or fevers attended by cerebral determination and severe or protracted delirium. This consecutive state of dementia has been termed fatuity: it was confounded with idiotcy, until ESQUIROL very accurately distinguished between them; and showed that dementia is exhaustion or obliteration of an intellect which was once sound, by intense mental causes, or by maniacal or other diseases; whereas, idiotcy is a congenital state of fatuity, or an original want of the intellectual powers. The idiot, he remarks, has never possessed the faculties of the understanding sufficiently developed for the display of reason. The victim of dementia was once endowed with them, but has lost this possession. The former lives neither in the past nor in the future; the latter has some thoughts of times past, reminiscences which excite in him occasional gleams of hope. The idiot, in his habits and manners of existence, evinces the semblance of childhood; the demented person preserves, in his conduct and acts, the characteristics of consistent age, and bears the impress derived from the anterior state of existence. Idiots and Cretins have never possessed memory, judgment, sentiments; scarcely do they present, in some instances, indications of animal instincts; and their external conformation plainly indicates that their organisation is incapable of thought.

152. M. ESQUIROL has distinguished *three varieties* of dementia, — viz., the *acute,* the *chronic,*

and the *senile*, — either of which may be *simple*, or *complicated* with melancholia, mania, epilepsy, convulsions, scorbutus, and especially with general paralysis. — The *first variety*, or *acute dementia*, is caused by gross irregularities of regimen, diet, &c., by fever, hæmorrhages, by metastasis, suppression of accustomed discharges, and a lowering treatment of mania. It is sudden in its attack, is unattended by lesion of movement, and is curable by means of regimen, exercise, and restoratives, by the removal of the cause, &c. — The *second*, or *chronic dementia*, is either primary, or consecutive upon the diseases just mentioned, more frequently the latter. When it succeeds other forms of insanity, as mania or monomania, it preserves some traces of the character of the primary disorder, or of the dominant idea during the previous affection. When it is caused by drunkenness, it presents peculiar characters, the chief of which are general tremor, false perceptions, rapid pulse, general perspiration, &c.; and it closely resembles *delirium tremens*, — which, indeed, may be more correctly viewed as an acute form of dementia, than as a distinct malady. When dementia arises from this cause, it more frequently assumes an acute and a curable form, than a chronic and persistent state, — a circumstance which seems to have escaped M. Esquirol.—The *third variety*, or *senile incoherency*, comes on gradually with the progress of age, and shows itself in the loss of memory and of sensibility, in the weakness of the impressions and sensations, of attention and perception; in the vacillations, and uncertainty of the will; and in the slowness and incapability of motion.

153. Dr. Prichard considers that incoherency presents *four stages*, or *degrees*, consisting of different phenomena; the description of the one stage not being applicable to the other. If the disorder commences in the first degree, it goes on successively to the more advanced; but the more severe degrees may appear at once, as the immediate effects of causes which destroy the powers of mind, or produce disorganisation of the brain. —The *first stage*, or degree, he remarks, may be termed that of *forgetfulness*, or loss of memory. Its chief characteristic is a failure of memory, especially as to recent events.—The *second stage* brings with it a total abolition of the power of reasoning, depending on a loss of voluntary control over the thoughts. It may be termed the state of *irrationality*, or *loss of reason*.—In the *third degree*, the individual is incapable of comprehending the meaning of any thing that is said to him. It may be styled the stage of *incomprehension*.—The *fourth stage* is characterised by loss of instinctive voluntary action. The individual is destitute of even the animal instincts; he cannot obey the calls of nature. This is the stage of *inappetency*, or *loss of instinct or volition*.

154. The *first* of these, however, does not amount to dementia. It is often a premonitory state, or stage, which passes into complete incoherency or imbecility; but it as often continues simple, and stationary, without passing into more marked disorder. This is especially the case in old persons. They often lose their memory, particularly of recent events; and their sensibility, and the power of quick or rapid movement, become impaired. Recent impressions in them are weak; and hence they live upon past recollections, which they have pleasure in recalling. But their powers of reason and their judgment are not materially weakened; and, until these become very manifestly affected, they cannot be viewed as presenting even the slightest form of this species of insanity.—The *second* and *third grades* of dementia particularised by Prichard, are the common forms in which the disease occurs in either its primary or its secondary states. In these the powers of reason are lost; and the patient is as unable to control his ideas, as he is incapable of comprehending the meaning of any thing to which his attention may be called. The *fourth grade* is identical with the variety of general insanity about to be noticed, under the head of *Fatuity*, or annihilation of the powers of mind (§ 164.).

155. *α*. The *slighter forms* or *grades* of dementia, or *incoherency* and *imbecility*, are evinced by a loss of control over the ideas, and of the faculty of attention. The individual occasionally apprehends something of the meaning of a question; but, before he has uttered half his reply, he becomes confused or bewildered, and is turned aside from it by some accidental or new suggestion. His expressions are consequently irrelevant and absurd. In this state, his memory may not be altogether lost, though very much impaired, and glimmerings of reason are occasionally evinced. He affixes some meaning to his expressions, but he soon loses or forgets it. He may know his friends, but he displays no signs of sensibility or of emotion on being visited by them. In such cases, the *incoherency* is remarkable. In others, the impairment or loss of the powers of consciousness and of intellection (see note, § 66.), and a state of intellectual *imbecility* are more or less manifest. — Some patients, in these states, are capable of being employed in mechanical occupations, and particularly in what they had previously been habituated to; but even in these their imbecility is often conspicuous. Others, particularly when dementia is consequent upon mania, experience occasional paroxysms of excitement, in which the symptoms of more active mental disorder become prominent.

156. *β*. The *severer* or *confirmed states* of dementia are characterised by inability to comprehend the meaning of any question, however simple. Reason is entirely lost, and the person acts from instinct or habit. The physical activity is often remarkably displayed in this state of the disease. Some jump or run to and fro, or walk round in a circle; or dance and sing, or occasionally vociferate. Others cry or laugh by turns, or almost at the same time, or utter the most unmeaning jargon, or words without ideas, or mutter broken sentences, or expressions without any connection, or evincing the most trivial association, which may depend upon accidental sound, or some sensible object attracting momentary attention. Many sit in silence, with a sedate look, or a vacant smile, or an unmeaning stare, and hardly utter a word for weeks, months, or even years. Some crowd round a stranger and gaze at him, having intelligence barely sufficient to perceive something new; and others have a propensity to ornament themselves in a strange or a fantasticmanner, or to add whatever may be in their way to their dress, which is always singular or ridiculous. A few continue crouched in a particular posture, which they always prefer, though it seems the most un-

easy or painful; and, if placed in a different position, they soon resume their accustomed posture.

157. *γ*. The disorder of the sensibility and of the understanding is, to a certain extent, pourtrayed in the *countenance*. The features are motionless and devoid of expression. The look is wandering or vacant. The face is pale; the eyes are dull and moistened with tears; the pupils are dilated; and occasionally the features are distorted from relaxation of some of the facial muscles. The body is thin and emaciated in some cases, and full and fat in others. In these latter, the face is full, and the conjunctiva occasionally loaded. In a few, but little indication of mental disorder is evinced by the countenance.

158. *δ*. The *bodily*, and especially the *organic*, *functions*, are not materially disturbed. Sleep is sound and prolonged. The appetite is unimpaired, or it is increased almost to voracity. The alvine evacuations are free, sometimes fluid; and in many cases corpulency supervenes. Occasionally, when mania or monomania is about to pass into dementia, the transition is indicated by obesity. When paralysis appears in the course of the disease, the paralytic symptoms manifest themselves slowly and successively. Articulation is first impaired, afterwards locomotion is executed with difficulty, and, lastly, the evacuations become involuntary. But this complication is only contingent, and as such will be noticed hereafter.

159. *ε*. The *course* of dementia is occasionally *acute*, but much more commonly it is *chronic*. It is *simple*, or *complicated* in the manner about to be noticed. It is generally *continued*, but it is sometimes remittent, or even intermittent. Its duration is most various, from a few days or weeks, to many years.

160. *b*. The *Diagnosis* of dementia cannot be difficult, excepting at the time when mania or monomania is passing into this state; and then the symptoms will indicate the predominance of either. Maniacs and monomaniacs are carried away by false sensations and perceptions, by illusions and hallucinations, by the excitement, the exuberance, and the determined character, of their ideas and of their emotions: the demented person neither imagines nor supposes any thing: he has almost no ideas; he neither wishes, nor determines, but yields to every the slightest impulse or suggestion: his cerebral power is exhausted. In the maniac or partially insane, every thing announces power and strong effort; whilst, in the demented person, every thing betrays relaxation, feebleness, or complete mental impotence.

161. *c*. The *Causes* of which dementia is more especially the consequence, are either moral or physical; but the two orders are often associated, or the one is accessory to the other, in their operation.—*Moral causes* affect females more frequently than males, and the higher than the lower ranks of society; but are much less influential in occasioning this than the other forms of insanity. They are chiefly — excessive or frequent excitements of the passions, domestic unhappiness, political commotions, frights, sudden grief or joy, disappointed affection and ambition, misfortune and want.— *Physical causes* are the most concerned in occasioning this species of insanity. The progress of age, fevers with cerebral determination or predominant affection, congestion and chronic inflammation of the brain and its membranes, the cessation and disorders of the catamenia, are the most common of this class. After these follow — masturbation and venereal excesses, the abuse of intoxicating liquors and of narcotics, the excessive use of mercurials, parturition and the accidents consequent upon it; epilepsy, apoplexy, palsy, injuries of the head, and excessive or prolonged mental exertion, especially when prematurely commenced, or before the brain is duly developed, suppression of cutaneous eruptions, of gout or rheumatism, and of accustomed discharges, have likewise caused, or contributed to cause, dementia. This species of mental disease is, however, most frequently consequent upon mania, or some one of the several forms of partial insanity, especially when these have been treated by too large sanguineous depletions, or by other too active and lowering means.

162. Hereditary conformation or influence, the phlegmatic and lymphatic temperaments, debility caused by irregularities and excesses, and exhaustion of cerebral power by these or by inordinate indulgence of the passions, weak, timid, or irresolute constitutions of mind, and original feebleness of the intellectual powers, *predispose* to dementia.

163. *d*. The *Prognosis* of dementia is extremely unfavourable, especially as respects the more severe cases. In the milder states or stages of the malady, a few instances of recovery occur, especially when a paroxysm of acute mania supervenes. The apparent reaction of the system is, in these cases, sometimes followed by perfect rationality. Attacks of fever attended by delirium are often fatal to lunatics; but of those who recover from them, not a few have their faculties restored to them. When the physical health of persons in dementia improves at a time when the mental disorder seems to be increasing, and especially if they eat, sleep, and digest well, and become fat, recovery may be almost despaired of. If any of the *complications* about to be noticed take place, recovery can no longer be anticipated. Even in this state, patients may linger for many months, or even years, until carried off, by the extent of cerebral lesion, or exhausted vital power, or by the complications of the malady, or rather by the organic alteration on which the complications more immediately depend.— The *changes* found on dissection of fatal cases will be described hereafter.

164. C. FATUITY, or *Annihilation of the Powers of Mind*. — This may be viewed as the last stage, or an extreme degree of dementia, but it sometimes follows almost immediately upon mania or some one of the forms of partial insanity. — *a*. In this state, all the mental powers, and even most of the animal instincts, are lost. The individual continues to possess a state of organic existence, but deprived of all the functions of the brain, and nearly of all the functions of sense. He is scarcely conscious, evinces little or no desire or aversion; is often unable to control, or is not cognisant of, the calls of nature. One stands in a state of vacant unconsciousness; another sits rocking himself to and fro, or yelling or chanting unmeaning words; a third is quite motionless, with his head hanging on his breast, or with his eyes and mouth half open. In this state, the patient is often destitute of the feelings of hunger or thirst, and occasionally even of that of pain. He may linger in this condition for years, but he can never altogether recover from it. A few may be roused, by favourable circumstances, to a less extreme state of mental

annihilation than I have described, — to a state of dementia above this in the scale of intellectual privation, — but a relapse always occurs after a short time.

165. *b.* Fatuity is often *complicated* with partial or general paralysis; and, occasionally, attacks of convulsion or of epilepsy take place, and sometimes terminate this state of existence. In most instances, and especially when fatuity is complicated, the countenance assumes a peculiar character, owing to the absence of all action in the muscles of the face, to the general relaxation of the features, and to the laxity of the integuments of the cellular tissue. The whole frame indicates, by a flabby state of the tissues, the exhausted condition of cerebro-spinal nervous power. — The organic functions are generally but little disordered, excepting as respects the processes of excretion. Owing to defective voluntary control, and the unconscious state of evacuation, the patient often presents a state of disgusting filthiness, difficult to be prevented, and requiring strict attention, in order that the consequences to which neglect uniformly leads may be warded off.

166. ii. COMPLICATED INSANITY.—The several forms of insanity — of the partial as well as the general disease — are often variously complicated. Not only may the different varieties of partial insanity be associated in numerous modes; but general insanity may present, especially when consequent upon monomania, a predominance of disorder as respects certain ideas, feelings, or trains of thought. I have already shown, that moral insanity often passes into disorder of the understanding; and that, in such cases, not only both states of derangement subsist, but some additional disorder, in many instances, is at last superadded. Thus, states of general alienation, more or less complete, are often ultimately developed, presenting either of the states of mania or of dementia, often with prominent disorder on certain subjects, or a disposition to entertain certain emotions or ideas in preference to any other. These states of alienation, however, can hardly be denominated complications, inasmuch as they are various modes in which the mental disorder generally goes on increasing, when uncontrolled by treatment, until the powers of mind are altogether overturned, or even annihilated. The morbid associations, therefore, to which I now proceed to direct attention, are strictly complications, or contingent associations of bodily disease with insanity, and are of so frequent occurrence, and of so great importance in regard of the course and termination of the cases in which they are observed, as to require a particular notice. The circumstance, also, of the mental disorder, and the contingent bodily disease, generally proceeding from a source common to both, — from derangement of the circulation within the cranium, and often from organic lesion, either intimate and hardly appreciable, or gross and obvious, — also demands a more special consideration of this subject.

167. *A.* The COMPLICATION WITH GENERAL PARALYSIS is the most common and the most important of any that occurs in practice. I have already fully described its different *stages* or *degrees* (§ 33. 36.), and shall notice, at this place, certain particulars only that did not fall within the scope of that description. This form of paralysis is often indicative of chronic inflammation of the meninges, and is distinct from the paralytic affections consequent upon cerebral hæmorrhage, or upon softening, tumours, &c. of the brain, — which, however, may also be complicated with insanity, although much more rarely than the general form of the affection above described. It, in a few instances, precedes, and in most supervenes upon, the mental disorder. It sometimes appears with the first symptoms, or during the acute period, of insanity; and generally commences in the manner I have stated (§ 33.), and increases as the mental powers diminish. Whatever form the mental disorder may have presented, it soon passes into chronic dementia, when complicated with paralysis. It generally terminates the life of the patient within three years; death being preceded by cerebral congestion, convulsions, diarrhœa, and gangrene of those parts sustaining the weight of the body when muscular support has been lost. This form of paralysis is much more frequent in men than in women. Of 109 insane paralytics under the observation of M. ESQUIROL, during three years, at Charenton, 95 were males. Of 609 lunatics admitted at this institution, in three years, 109 were paralytics; — the proportion in males and females being — in 366 male lunatics, 95 were paralytics; and of 253 females, 14 were thus affected. Of 334 lunatics in the Asylum of St. Yon, near Rouen, 31 were paralytics, — of whom 22 were men, and 9 women. At the Bicêtre, the proportion of paralytics to the number of lunatics is much smaller. It is observed by M. ESQUIROL, that this complication occurs most commonly in those lunatics who have caused their insanity by venereal excesses, by intoxication, by the abuse of mercury, and by mental exertion, — circumstances which account for the greater prevalence of it in males than in females. The lunatics at Charenton, where it is most frequently observed, have been in easy circumstances, and have possessed means of gratifying their passions, or have exercised professions which have excited or over-exerted the brain, without duly exercising the body.

176. According to M. CALMEIL, this affection has generally, at Charenton, appeared soon after the commencement of insanity; but it sometimes has not occurred until insanity has continued for many years. A few individuals have displayed all the vigour of intellect for some time after they were attacked by it, and derangement has afterwards taken place. If the mental disorder has not already proceeded, it very rapidly proceeds, in this complication, to advanced or complete dementia; yet persons thus affected preserve their appetites, or have them greatly increased. They are in all other respects in health. The circulation is natural, and the sleep undisturbed. They continue plump, but the soft solids are flabby and soft; and, as the disease proceeds, they are liable to constipation, often followed by diarrhœa, by unconscious evacuations, and by want of power over them, owing to palsy of the sphincters. Retention and incontinence of urine generally also take place, and aggravate the evils to which the paralytic person is liable.

168. *a.* The *duration* of this complication is various; but is reckoned by MM. ESQUIROL and CALMEIL to average about thirteen months; very few surviving longer than three years with it.— The ultimate *prognosis* is most unfavourable. M. ROYER-COLLARD, after an experience of twenty

years, had not met with one instance of recovery from it. M. CALMEIL has seen only two cases, thus complicated, that recovered; and M. ESQUIROL has mentioned only three. The appearances observed after death will be stated hereafter.

169. General paralysis is apparently more frequent in Paris than elsewhere. There can be no doubt, however, that it has been more accurately observed amongst the insane in that city, and indeed through many parts of France, than elsewhere. Dr. BURROWS had stated it to be comparatively a rare disease in England. M. ESQUIROL doubted this, and inferred that it was considered rare, because it it had not been accurately observed in this country. There is much truth in this, as shown by the recent inquiries of Dr. PRICHARD. This physician states, that he had made many inquiries with a view to determining this question, but had met with considerable difficulties in obtaining satisfactory information. The facts, however, which he has adduced, prove that this is a frequent complication of insanity in this country, although not so frequent as in Paris; and in every respect confirm the accuracy of the observations furnished by MM. ESQUIROL, CALMEIL, and other French pathologists.

170. *b*. There is a modification of paralysis, as Dr. PRICHARD truly remarks, of frequent occurrence, during protracted insanity and dementia, in English hospitals for lunatics, that differs in duration, and in some of its features, from the general paralysis so accurately described by the French writers. It resembles the debility or decrepitude of extreme old age. Patients affected by it, sit crouched with their heads hanging down; and when they attempt to raise themselves into the erect posture, their limbs tremble, they stoop, and totter. Some stand leaning against a wall for whole days, with their bodies curved forward, their heads and necks hanging down, and their upper extremities shaking and hanging useless. Such patients are always in the most advanced stage of dementia, and often continue in this state of paralytic decrepitude for many years. Some become bedridden, and remain long incapable of any voluntary movement, until at length either the powers of life are gradually extinguished, or they are carried off as in the form of paralysis previously described (§ 33.).

171. *c*. Paralysis from cerebral hæmorrhage, from softening, from tumours, or from other organic lesions of a portion of the brain, is also observed in insane patients, but not so frequently as the varieties of this affection already noticed. In these cases, it generally assumes the form of hemiplegia; but it sometimes continues in a partial or limited state,—being confined to one arm, or to the muscles of one side of the face, or to the arm and face, for a considerable time. It may even proceed no further, although more commonly it passes into palsy of the whole side. In these the attack is gradual, slow, and *chronic;* and usually proceeds from softening, or from some other change of structure, in a portion of the brain or of its membranes. In other cases, the paralytic affection is more sudden and *acute,* and is consequent upon an apoplectic or comatose state, or upon an epileptic or convulsive seizure. It may be at at once hemiplegic; or it may be at first more partial, and become more complete, either gradually, or after relapses or repeated attacks of sopor or convulsion. This more acute form of palsy seems to proceed from congestion or sanguineous effusion in the brain; but it has occurred without any organic lesion having been found to account for it. (See *Appearances in the Brain, in Paralytic* INSANITY.)

172. The more usual forms of paralysis may precede the insanity; but they most frequently take place in the more confirmed and chronic states of mania, and especially in dementia and fatuity. They are evidently more or less intimately connected with the pathological conditions upon which insanity depends, as well as with the consequences which these conditions produce, as will be shown hereafter. Whilst palsy in the insane is generally incurable, insanity is equally so when thus complicated.

173. *B*. VERTIGO, or *Giddiness,* often precedes and accompanies insanity. The two forms of vertigo — the one from active congestion of blood in the brain, the other from a defect of the supply of blood to this organ — may attend mental diseases. It is extremely necessary to distinguish between these two opposite conditions of the cerebral circulation, with reference to this affection. When vertigo proceeds from the former state, it is characterised by a sense of rapid gyration in the head, by throbbing in the temples, a beating noise in the ears, succeeded sometimes by vomiting or nausea, and occasionally by loss of consciousness: when it arises from the opposite condition of the circulation, it resembles a gradual swimming,—objects appearing as approximating, or receding from, the organs of vision, or becoming dark, — and is attended by a sense of faintness. It is requisite to attend to these two very different forms of vertigo, inasmuch as they indicate important and opposite states of the cerebral circulation; and, as in the more partial forms of insanity, they often precede the accession of mania, or the occurrence of some dangerous complications.

174. *C*. EPILEPSY and CONVULSIONS are frequent complications of every variety of insanity. Either of these affections — either the regular paroxysm of epilepsy, characterised by sudden loss of consciousness, frothing at the mouth, injury of the tongue, and subsequent sopor; or the more gradually developed fit of convulsion, in which these phenomena are not present — may precede or follow the mental disorder. In every instance, congestion or determination of blood to the head becomes remarkable during the paroxysm, although there may have been a deficient supply of blood to this quarter shortly before. The occurrence of these complications is generally owing to insolation, to suppression or disorder of the catamenia, to violent excitement or exercise, especially during warm weather, to injudicious bathing, to the use of intoxicating liquors, to venereal excesses and masturbation, to habitual gluttony or excesses at table, and to the other causes enumerated in the articles on these diseases. Epilepsy occurs most frequently in those who have complained of vertigo, headach, incubus, and of restless dreaming sleep; and an attack is generally preceded by some of these symptoms, or by an aggravation of mental disorder.

175. Insane persons, predisposed to epilepsy or convulsions, as well as epileptics disposed to insanity, generally present a peculiar prominence of the eyes, sometimes with a puffy or wrinkled state

of the surrounding integuments, partly arising from congestion of the blood-vessels, and particularly of the veins, in the vicinity. This is observed also in mania, and still more so in epileptic mania. The eye also has a kind of glaze over it, distinguishing it from the convex eye of near-sighted people.

176. When an attack of epileptic or other convulsions is followed by mania, or any other form of mental disorder, the latter often disappears, sometimes in a few days or weeks, under judicious treatment; but it always returns with the convulsive affection, — and after repeated attacks, the mental disorder becomes more severe, more general, as respects the mental powers, and more confirmed, until the patient rapidly sinks into dementia or fatuity, in which state apoplexy, or some one of the forms of palsy, is sometimes superadded. In this case, life is terminated, after an uncertain time, either by a paroxysm of convulsion, or by one of the later complications. Although epileptic mania generally pursues this unfavourable course, when neglected or injudiciously treated, yet it sometimes admits of alleviation, or even of cure, when judiciously managed. — When epilepsy or convulsions occur in the course of any of the more chronic forms of insanity, the latter is very rarely cured; if death does not take place soon, it lapses into complete dementia or fatuity.

177. Mania complicated with epilepsy is characterised by ferocious, malign, and often murderous paroxysms, or exacerbations, which frequently take place most suddenly. The fury of the patient is sometimes directed against himself; but oftener against others, especially those he most loves when sane. Dr. Burrows observes, that when paroxysms of mania suddenly attack persons subject to epilepsy, a reckless fury is exhibited by them, different from the characters of true mania. It seems as if the epileptic impulse, when not ending in convulsion, acts upon the brain in a peculiar mode, imparting to it that particular action denominated epileptic mania. The most horrible actions have proceeded from this complicated form of insanity. Sometimes the destructive paroxysm or impulse is produced by some fanatical opinion or idea, prompted by a misconstruction of some scriptural passage, by some delusion, or waking dream. Persons thus affected may have lucid intervals of considerable duration. But although the paroxysms are sometimes preceded by some signs or symptoms, yet they are often so sudden that mischief is occasionally done before it can be prevented. Hence epileptic maniacs should not associate with other insane persons, — and especially as the sight of epileptic paroxysms may produce the like in other maniacs. The appearances observed after death in epileptic and convulsive insanity will be noticed hereafter.

178. *D.* Apoplexy may be the *cause* of insanity, or it may be the *consequence* of those intimate lesions of structure which either occasion, or are connected with, the mental disorder. Esquirol considers that apoplexy constitutes a sixth of the physical causes of mental alienation, and an eighth of the deaths. Dr. Burrows thinks, that it is not so frequently a cause of insanity, or of death, in this country, as M. Esquirol states with reference to France. When apoplexy is connected with the production of insanity, it is generally congestive or hæmorrhagic; and, in the latter case, is generally followed by paralysis, — the mental disorder being complicated with hemiplegia, or with a more partial form of palsy. Apoplexy with effusion of blood generally occurs early in the mental disorder, and commonly in the maniacal form. When apoplexy precedes mania, there is often a great change perceived in the moral and intellectual character, for some time before the attack. Dr. Burrows justly remarks, that this change in the character may usher in an apoplectic as well as a maniacal paroxysm; and hence the affinity between sanguineous apoplexy and mania is evident.

179. The sudden deaths, however, which take place in chronic mania, and in confirmed dementia, and in the complication of insanity already noticed, are seldom produced by cerebral hæmorrhage. They were formerly ascribed to *serous* apoplexy; but as I have shown (see Apoplexy, § 115.) that the form of this disease, usually imputed to the effusion of serum, depends rather upon exhausted organic nervous power, in connection with congestion, or interrupted circulation of the vessels of the brain, than upon effusion, — which, even when present, is seldom in such quantity as to account for the fatal event, — so it may be inferred that sudden deaths in these chronic forms of general insanity are chiefly owing either to congestion, or exhaustion of nervous power. The fatal attack either commences with sudden or profound coma, which is soon followed by convulsions; or it begins with convulsions, which are soon succeeded by coma, rapidly terminating in death, — the apoplectic or the convulsive state being thus consecutive, or both, in a few instances, being simultaneous. Either of these forms of attack is often immediately consequent upon a paroxysm of furious mania, or of delirious excitement; and, in some cases, a state of acute or furious delirium, or of insane agitation, terminates at once in death, without convulsions or coma — at least, of any appreciable duration — having preceded the fatal event. This termination, which may be viewed as a form of apoplexy, has been noticed by Pinel, Esquirol, Burrows, and others, who have described it as occurring only in old and cachectic cases, and as being preceded by a sudden accession of maniacal or delirious excitement, which soon ceases, and the patient dies, as if from exhaustion of vital energy. On dissection, but little is found in the brain to account for the event; and the body soon passes into putrefaction. These forms of apoplectic attack are identical with those which I have ascribed, in the article Apoplexy, to exhaustion, or loss of the organic nervous energy of the brain, — a state formerly noticed by Boerhaavf, and designated by him *Apoplexia defectiva.*—It is probable, however, that, in the cases of insanity, in which the sudden death is consequent upon distinct evidence of general cachexia, the event is caused rather by sudden privation of power in the heart, or by sudden congestion of the lungs, or other affection of these organs, than by loss of the nervous energy of the brain.

180. A state of profound and continued *coma* occurs in the course of a few cases of insanity. It may follow mania; and I have seen it, in one instance, consequent upon moral insanity. I believe that it takes place chiefly in those states of mental disorder which have been produced by depressing

causes. The two cases which I have had an opportunity of observing, have been prolonged, and evidently owing to exhaustion of the vital manifestations of the brain. Restoration took place from this state, but the powers of the mind were never, even partially, recovered. The *apoplectic* and *comatose* complications, especially of chronic mania, of dementia, and of fatuity, — particularly when terminating quickly in death, or characterised by sudden collapse or exhaustion of nervous power, — occur most frequently in winter and during cold weather, and are occasioned chiefly by causes which depress or exhaust the powers of life.

181. *E.* HYSTERIA, CATALEPSY, and CATALEPTIC EXTASY also occasionally precede, and occur in the course of, insanity. The two latter affections, however, are rarely met with, but have been observed by HALLER, BOERHAAVE, LIEUTAUD, TISSOT, PARRY, BURROWS, and myself,— chiefly, however, as antecedents of insanity. Hysteria is observed most frequently at the commencement of mental disorder; and it sometimes passes into a state of moral or partial insanity, which after a time subsides. Hysteria is often associated with hypochondriasis; and both when thus associated, and when severe and prolonged or habitual, insanity is occasionally consequent upon, and subsequently more or less manifestly complicated with, it. It is of the utmost importance, in practice, to recollect the connection, when females come under treatment. In these cases, the mental disorder, as well as the hysterical affection, proceed from a common source: uterine irritation or disease is propagated to the cerebro-spinal nervous system, and the functions of the brain are consequently more or less disturbed.

182. *F.* DISORDER OF THE DIGESTIVE AND ASSIMILATING ORGANS very generally *precede* and *complicate* disorders of the mind. I am persuaded, that much too little importance is attached to this circumstance, in respect both of the pathology and treatment of insanity. The organic functions are often generally deranged — commonly more or less weakened — long before the mind is affected. Digestion is impaired, although the appetite may be natural or even increased; and the bowels are generally torpid, and require large doses of purgatives to act upon them. They are sometimes irregular, from irritation of the digestive mucous surface having reached a considerable pitch, or from the presence of offending matters. The secreting and assimilating functions of the liver are likewise impaired; — the bile is either scanty, or retained in the ducts or gall-bladder, until it acquires irritating and morbid states; and the vital influence of this organ on the venous blood circulating through it is insufficiently exerted. Hence the chyle is imperfectly prepared, and the blood abounds either in unassimilated elements, or in materials which require to be eliminated from it. To these circumstances especially are to be attributed much of the disorder consecutively observed in the functions of the brain, of the lungs, and of the heart; and, at length, many of the organic lesions of these organs, which complicate, and ultimately terminate, the more severe cases of mental disease. The general *cachexia* often preceding insanity, and still more manifestly attending it, is the result of the morbid states of the chyle and blood consequent upon deficient organic nervous energy throughout the digestive and assimilative organs. Many of the structural changes, as well as the scorbutic state of the body, which very often take place in the more chronic cases of insanity, proceed from the morbid conditions of the fluids, consequent upon this impaired state of nervous power.

183. BROUSSAIS, and most of his followers, have attributed the disorder of the digestive organs preceding and attending insanity, to *chronic inflammatory irritation of the gastro-intestinal mucous surface;* and have even considered the mental affection to be frequently symptomatic of, or caused by, the disorder of this surface. Without disputing the occasional presence of chronic gastro-enteritis, both previously to, and associated with, mental derangement, I believe that, when it is present, it is chiefly contingent upon the state of organic nervous influence just contended for, and upon the irritating state of the contents of the alimentary canal, arising out of imperfect digestion, and a morbid condition of the secretions poured into it. This subject, however, will be further noticed hereafter.

184. *G.* There are *various other diseases* which arise in the course of insanity — or are contingent upon it, — and which even cause its fatal termination in many instances. The chief of these are consumption, diseases of the bowels, scurvy, organic lesions of the heart, dropsical effusions, gangrene, &c. These are actually complications, inasmuch as the mental disorder generally proceeds in connection with them for a longer or shorter period, and as they have little or no influence in terminating the mental disorder otherwise than in death. Some of them, particularly diseases of the lungs and pleura, may suspend it, or cause it to intermit, but they have no further influence over it, of a beneficial kind. They, however, often tend to aggravate it, or to cause the slighter and more partial forms to pass into those more general and severe. I shall notice them further in the following chapter.

185. IV. TERMINATIONS OF INSANITY.—i. PROGNOSIS. — Insanity terminates either in *recovery* or in *death;* but it may be said to terminate otherwise, when one variety lapses into another, especially into one of a severer or more complicated form, or when one alternates with another. Although this transition of one state of disease into another closely allied to it, cannot be strictly considered as a termination of it, yet it requires notice, as possessing great practical importance. Much of the information upon which opinions are to be formed as to the results of mental disease, is furnished by the statistics of lunatic asylums — sources of notorious inaccuracy in this country, especially up to a very late period. Much of this inaccuracy arises from the regulations by which those institutions are governed, — from the classes of patients which they receive or reject, — and from the periods their inmates are allowed to remain under treatment. Many recent cases, both acute and slight, are treated in private practice, and recover in a short time, which do not come into any account either of the number affected, or of the number cured. The systems of treatment pursued in different asylums, public and private, and in states of individual seclusion, are so diversified, — in many instances, most inappropriate — in some, calculated to aggravate and perpetuate the malady — in others, altogether inert — in numerous

cases, without the least reference to very manifest physical disorder, characterised by obvious symptoms and signs — and in not a few, without regard to intellectual or moral guidance, — that numerical results obtained from these sources may flatter those who rejoice in a parade of precise details, without considering the soundness of the data upon which they are calculated, or the fallacies which are involved in them, or the unsound inferences which they encourage and propagate, but can never satisfactorily inform those who look for instruction from unexceptionable, and from, at least, tolerably instructed, quarters. In a country, where the institutions — public and endowed as well as private and mercenary — for the greatest and most humiliating of human calamities, are shut against professional instruction, — where these institutions, and those to whom their medical management is intrusted, furnish the least possible modicum of professional information, — where asylums are made more for the profitable and safe custody of the inmates, than for their recovery, — what can be hoped from statistical and numerical statements, but mystification, if not positive deception. Whilst, therefore, I adduce such information as I can obtain, I give it with due note of its imperfections, that it may not be estimated above its real value. There are, however, some sources — especially those to which most frequent reference is here made — that deserve somewhat more of confidence than should be reposed in many others.*

186. *A.* The Duration of insanity is most various. The disease has subsided, in some cases, within a few days from its commencement; in others, it has continued for twenty, thirty, or even forty years. — *Recoveries*, as well as *deaths*, occur at all periods from the commencement of the malady. If neither of these events takes place at a somewhat early period, confirmed insanity generally succeeds, and sooner or later assumes the form of dementia, and sometimes ultimately passes into a state of fatuity. In this case, the malady goes on until it terminates in *death*, which takes place either in its simple or complicated states.

187. *B.* Recovery is the result in a large proportion of cases of insanity; but the proportion varies remarkably in the several forms and complications of the malady. It is very important, in respect both of the history and classification of the disease, and the *prognosis*, to determine, as accurately as possible, the number of cures in a given number of cases. But before the general results furnished by the imperfect sources already alluded to, or the estimates made from the reports of lunatic institutions, be at all considered, it will be preferable to take a view of the several circumstances which influence the event of the malady, but which vary in character, in combinations, and in their effects, in different countries, climates, places, and asylums. These circumstances are — the particular kind of mental disorder; its causes, predisposing and exciting; its duration, continuance, or recurrence; its existence in a simple or in a complicated state; the physical disease with which it is associated; and the age, sex, constitution, occupation, &c. of the patient.

188. *a.* The *form of the disease* has a marked influence upon its curability. M. Esquirol states that a greater proportion of the cases of mania is cured than of any other form of madness, and that dementia is scarcely ever cured; but, of 518 recoveries at Charenton during eight years, the numbers were — 263 cases out of 545 of mania; 251 out of 715 of monomania; and only 4 out of 281 of dementia. But of the aggregate of 1557 cases, there were 274 paralytics, 62 epileptics, and 15 idiots; so that the curable cases were 1205, and of this number upwards of two fifths were cured. He further remarks, that the greater sanability of maniacs comparatively with monomaniacs had place chiefly in males; monomania being, from this, more curable in females than in males. The following table will give a more precise idea of the results obtained by M. Esquirol at Charenton: —

Form of Disease.	Male Cases.	Female Cases.	Total Cases.	Males recovered.	Females Recovered.	Total recovered.
Monomania -	372	343	715	123	128	251
Mania - -	334	211	545	160	103	263
Dementia and Fatuity -	227	69	296	1	3	4
General Total -	933	623	1556	284	234	518
Deduct Incurable Cases -	-	-	351			
	-	-	1205	-	-	518=1 : 2·34

189. *b.* The *causes* have a manifest influence upon the event in mental disorder. But they are so variously associated in producing their effects, that it is very difficult to advance any precise statement on this topic. Hereditary predisposition, and the more powerful physical and moral causes, especially when combined, must be viewed as unfavourable circumstances. Indeed, all the causes which I have enumerated as especially influential in occasioning dementia may be considered in this light.

190. *c.* The *age*, *sex*, and *constitution*, of the patient are material considerations in forming a prognosis. — The most favourable *age* for recovery is between the 20th and 30th year. But few recover after the 50th year. M. Esquirol states, that, of 209 recoveries at Charenton, the greatest number of cases were from the 25th to the 30th, and from the 30th to the 35th year. This is the period of greatest vital energy, when acute mania oftenest occurs. Recoveries diminish progressively from the 45th year. The diminution is more abrupt in females, and more gradual in males. Twenty men, however, recovered after the 50th year, in which number were 4 out of 12 lunatics who had exceeded 70; so that advanced age does not preclude hope.

191. Insanity is, generally speaking, more curable in *women* than *men*. When it is evidently connected with a condition of the natural functions which is susceptible of change by medical art, or by the efforts of nature, or the progress of age, a hope of cure may be entertained on these grounds. Thus recoveries have often taken place in females at critical periods. M. Esquirol men-

---

* On this subject, as well as on many others connected with insanity, much interesting remark will be found in an able analytical article in the 13th No. of the *British and Foreign Quarterly Review*, which came before me after a great part of this article was sent to press. It is at least consolatory, that the able author of this paper, and of an excellent work on Insanity, should be placed over the County Asylum.

tions instances of dementia in females which had continued from early youth, and had terminated on the appearance of the catamenia; and others which had commenced at that period, and had recovered when the catamenia ceased. When the disease has followed the suppression of an eruption or of an accustomed discharge, a cure may be hoped for, by re-establishing the suppressed evacuation or eruption, or by means which have a similar effect upon the constitution.

192. *d.* The previous *duration* of the disease has a marked influence upon the curability of it. The chance of recovery is very much greater in the early than in the advanced periods. Dr. Willis stated that 9 cases out of 10 were restored when they had been placed under his care within three months from the commencement of the attack; and Dr. Finch has declared that 61 out of 69 patients recovered who were received into his asylum within the same period from the appearance of the malady. Dr. Burrows, in his very excellent work, has reported 221 cures out of 242 recent cases. Dr. Prichard remarks, that 7 out of 8, or even a larger proportion, of recent cases have terminated successfully in the Retreat near York. This is as favourable a view of the result in recent attacks as can be entertained; and yet, when we consider that many recoveries from mental disorder take place in private practice without becoming known, and that the great majority of those cases which are admitted into institutions or asylums are either of some duration, or second or third attacks, or have withstood the treatment that had been adopted, it cannot be considered as being much too favourable as respects all very early states of this malady.

193. M. Pinel was the first, or amongst the first, to direct attention, by a memoir read at the National Institute in 1800, to the degrees of probability there existed of recovery at different periods of insanity. This eminent physician inferred, that a greater number of recoveries take place in the first than in any other succeeding month; and that the mean duration of the malady, in cases of recovery, is from five to six months. According, however, to M. Tuke and M. Esquirol, the mean duration of these cases is somewhat under one year. I believe that M. Pinel's conclusion is more correct as regards all instances of recovery, and especially as comprising recent cases, many of which are not comprised in the accounts furnished by public institutions; whilst M. Esquirol's inference is applicable chiefly to these and similar institutions. This writer states, that of 2005 female lunatics, 604 were cured during the first year, 497 in the second, 86 in the third, and 41 in seven succeeding years. From the tables furnished by him, and by Mr. Hitch, of the Gloucester Lunatic Asylum, to Dr. Prichard, as well as from other data, it may be truly inferred, that recovery is probable in proportion to the shortness of the duration of the malady. The importance of proper treatment at an early period, and the impropriety of sending a patient hurriedly off to a house of confinement, with no assurance of a proper system of treatment being persevered in, is very evident from these data, as well as from numerous other considerations. — A recent writer justly remarks, that cases are not wanting to prove, that the mind may recover even after many years have been passed in a state of insanity; and that such cases have sometimes been overlooked or concealed, there is too much reason to suspect. Instances are adduced by MM. Beaumes, Esquirol, and Chambeyron, in which recovery took place after madness had continued for twenty years, or even longer,— especially upon the establishment of a natural, or of a suppressed discharge, or of suppuration, or some extensive counter-irritation or evacuation. From Mr. Hitch's tables it would appear, not only that the greater number of cures occurred in recent cases, but that, in some, recovery took place in a short time after admission, although the disease had been of long anterior duration. Of five patients, insane for ten years, one was cured in nine months, one in ten months, the third in a year, and the other two in six months; and one who had been insane forty years was cured in four months. Three other cases recovered after eleven, seventeen, and twenty years. These facts are sufficient to prove that, from the long duration of the disease alone, recovery is not altogether to be despaired of.

194. *e.* The *complications of insanity* very remarkably influence the terminations of it. The association of any of the forms of the disease with general or partial *paralysis*, and of dementia especially with general palsy in any grade, is a most unfavourable circumstance, — recovery hardly ever taking place, as shown above (§ 168.), in any of these cases. — The complication with *epilepsy*, or *convulsions*, is also most unfavourable. When mania is consequent upon severe attacks of epilepsy, or when the maniacal affection is very violent in the intervals of these attacks, few or no hopes of recovery should be entertained. When, however, convulsions appear during the high excitement of mania, a somewhat more favourable opinion of the event may be formed. — The antecedence, or supervention, of *apoplexy*, or of *coma*, is a circumstance admitting of as few hopes as the preceding complication. — The occurrence of *phthisical symptoms*, or of obstinate *diarrhœa*, in the course of the mental disorder, especially when the latter is not followed by amendment, generally indicates a more or less speedy termination in death.

195. *f.* The *seasons* have a slight influence on the issue of insanity. Mania is more frequently cured in summer and autumn. The month of October presents the greatest number of recoveries; the month of February the fewest. Males are more frequently cured in July and November, females in October and May. Of 518 cures, M. Esquirol found, that 92 took place in winter, 123 in spring, 145 in summer, and 158 in autumn.

196. *g. As to the proportional number of recoveries in various countries and places*, great differences are found to exist; depending chiefly upon the restrictions, or the latitude, observed in public institutions, as to the admission and retention of patients. Dr. Burrows states, that 240 cures were affected, in his practice, in an aggregate of 296 cases of various kinds; 221 recovering out of 242 recent cases, and 19 of 64 old cases, or 81 in 100 of all cases, and 91 in 100 of those which were recent — a proportion much greater than that furnished by any other source; but very nearly agreeing with the statements of Dr. Willis. Dr. Jacobi considers that this high proportion can be explained only on the supposition that many patients were dismissed as cured upon the first appearance of amendment, or before recovery had

been fully established. He states, that in the asylum under his management, only 40 cases completely recovered out of 100, and six were alleviated. M. Esquirol states, that of 5360 admissions into French hospitals, 2691 were cured; and in the *Memoirs of the Academy of Medicine* (vol. i. p. 40.) he observes, that 4968 were cured out of 12,592 admitted into the Salpêtrière and Bicêtre, many of whom were idiots, epileptics, and paralytic, and fatuous aged persons. The same writer assigns 5918 recoveries to 16,516 admissions into English lunatic asylums. From this it would appear, that the proportion of cures formerly obtained in English institutions for the insane is much less than that furnished by the French hospitals. Dr. Prichard remarks, that this is the more remarkable, considering the peculiar regulations of Bethlem and St. Luke's.—These hospitals present restrictions unknown elsewhere. They reject all who have been more than a year insane; also those affected by paralysis, epilepsy, or convulsions, idiots, the aged and the infirm, as well as those discharged uncured from other institutions; and all persons who have not recovered at the end of one year are dismissed. Yet, on comparing the reports of these hospitals with those of other institutions where no selection exists, the relative number of recoveries is not found to be so great as might be expected. Dr. Burrows states, on the authority of Stowe, who derived his information from Dr. Tyson, physician to Bethlem Hospital, that, " from 1684 to 1703, 1294 patients were admitted, of whom 890 were cured, which is a proportion of more than two in three. But from 1784 to 1794, 1664 patients were admitted, of whom 574, or rather more than one in three only recovered :—This is remarkable. Dr. Prichard gives, on the authority of Mr. Lawrence, the report of this institution from 1820 to 1833 inclusive; and from that it appears, that the total number of admissions were 2445, of whom 1124 were cured, 643 were discharged uncured, 70 at the request of friends, 385 as improper objects, and 99 died. Deducting the 385 subsequently excluded, the 2060 furnished 1124 cures, or considerably more than one half.

197. In the following hospitals, where no selection of cases is made, the proportion of cures is — 43 in 100 in the Stafford Asylum; 42 in 100 in the Wakefield County Asylum; 40 in 100 in the Lancaster County Asylum; and about 48 in 100 in the Gloucester Asylum. The following table, furnished to Dr. Prichard by Mr. Tuke, gives the admissions and the results in the Retreat near York, from 1812 to 1833 inclusive : —

Classes of Cases.	Number admitted.	Recovered.	Died.	Removed.	Removed improved.	Remain.
1. Cases of less than three months' duration -	63	51	8	1	2	1
2. Cases of more than three, and less than twelve, months' duration - - -	65	28	10	6	3	18
3. Cases of more than twelve months' duration - - -	101	31	15	17	4	34
4. Cases of relapse -	105	58	17	13	1	16
Total - -	334	168	50	37	10	69

Mr. Tuke states, that several cases, entered as recent, were properly old cases; and if these were excluded, together with those connected with diseases speedily terminating life, as consumption and apoplexy, the probability of recovery from insanity, in recent cases, is greater than nine to one. An able reviewer very justly remarks on this statement, which is strongly confirmatory of that long since made by Dr. Burrows, that it is deserving of attention, as the opinion generally entertained, in respect of cases even of recent date, is more unfavourable than ascertained facts should warrant; the desponding view taken of such cases evidently tending to relax the efforts which should be made for the recovery of them.

198. *C.* The *particular prognosis*, or *the symptoms especially indicating recovery* from insanity, requires a brief consideration. — *a.* A paroxysm of mania may continue a few hours, or days, or weeks, or longer, and then remit or entirely vanish; or it may assume the form of melancholia, and continue or alternate with mania to its termination. It is impossible to say when either form of insanity will subside: the more furious, however, the attack, the shorter, generally, will be its duration, especially in mania. But when a remission of violence is attended by amelioration of other symptoms, it is a favourable sign. If the malady have continued several weeks, and the system is suffering, the disease will prove obstinate, if not dangerous. Insanity terminates favourably more frequently by a visible decline of the symptoms, and a remission or complete intermission, than by critical discharges. To these last, M. Esquirol attaches too great importance, Dr. Burrows too little, in this disease; for, although alvine, hæmorrhagic, urinary, and suppurative discharges, or boils and cutaneous eruptions, do not certainly remove the mental disorder, even when taking place spontaneously, yet they frequently do remove it. Fevers, hydropic effusions, and gout,—particularly the last,—have also sometimes removed the mental affection. These, however, as well as other diseases, have more frequently been followed by a remission, or, at best, by an intermission only.

199. *b. Remissions*, when thus or otherwise observed, may continue for days, weeks, or longer; but the reason still continues partially deranged, and the sleep disturbed by dreams, or by unpleasant sensations, referrible to the head or senses of sight or hearing; and after a time the disorder resumes its full force. — *Intermissions* are a perfect restoration of the faculties for a time, varying in duration from two or three days, or a month, to several weeks, months, or even years. Sometimes the return of the attack is after regular intervals, or, *periodic*; but as often it is irregular. Insanity may cease after a time, having passed first into a remittent or an intermittent state; or it may disappear, more or less rapidly, and completely, without any return. A gradual and perfect restoration of the faculties, however, takes place in the great majority of cases of recovery, without any recurrence or exacerbation of symptoms constituting the states of disorder just mentioned.

200. *c.* The absence of false perceptions and delusions is a favourable circumstance; but when they continue after the abatement of physical violence, a protracted case may be anticipated. A return of the natural feelings, of the affections, particularly to near relatives, and to former habits,

is amongst the surest indications of recovery. But in all cases, in forming a prognosis, the mental phenomena should be viewed in connection with the physical symptoms and state of the patient, and with such changes in the economy as have usually been viewed as critical in acute maladies, and particularly those affecting the brain or its membranes, — especially the restoration of suppressed discharges, evacuations, and eruptions; or the spontaneous occurrence of these, — as the hæmorrhoidal and catamenial fluxes, epistaxis, diarrhœa, furunculi, a regular fit of gout, &c. The utmost caution, however, should be observed in giving an opinion as to the event; but it is preferable to hold out hopes of recovery as long as there is a chance of it, otherwise the efforts to effect it may relax, and the patient consequently suffer. The following inferences are not materially different from those arrived at by Dr. Burrows and M. Esquirol.

201. 1. A cure is probable in proportion to the youth of the patient. — 2. It is also probable in a ratio with the recentness of the attack. — 3. The chance of recovery is the greatest in first attacks, and diminishes with each subsequent attack, and with the duration of the disease and age of the patient. — 4. Mania is cured most frequently; next, melancholia and monomania; and lastly, and the least, dementia and fatuity. — 5. Melancholia is difficult of cure in proportion to the degree of depression; a dread of poverty, of poison, and perverted ideas of religion, indicating an obstinate disease. — 6. Chronic insanity, whether mania or melancholia, seldom recovers. — 7. The prognosis of puerperal mania is favourable. — 8. Insanity with a propensity to suicide is not unfavourable, if the patient comes early under treatment, and the disease be recent. — 9. Acute dementia is curable; but chronic demency and senile insanity are never entirely cured. — 10. Hereditary predisposition protracts, somewhat diminishes the chances of, but does not prevent, a cure: relapses and recurrences are, however, more to be expected where it exists. — 11. When the insane are capable of judging rightly of their own state, a cure becomes difficult. — 12. An amendment of personal appearance, attended by an improvement in the mind, is indicative of recovery. — 13. When the insane preserve or acquire all their physical functions, and eat and rest well, and present their usual appearance, without recovering their faculties, recovery is hopeless. — 14. Insanity caused by excessive study, by the slow operation of moral emotions, or attended by hallucinations, by pride, &c., is seldom cured. — 15. Complications with palsy, and apoplexy, are incurable, and are fatal ultimately: but those with epilepsy, or convulsions, may recover in very rare instances. — 16. Men are more liable to relapses than women; one half of all relapses occurring in the first three months after recovery.

202. ii. Of Relapses and Recurrences of Insanity. — Recoveries from insanity are either *complete*, or *incomplete*. Of the latter, there are many, who, although perfectly rational, are never capable of returning to the sphere they formerly occupied, or of performing the duties which they previously fulfilled; their faculties having sustained a shock which can never be altogether recovered from. Dr. Prichard considers such cases to be about one tenth of the recoveries. Others remain longer or shorter in such a state of susceptibility that the slightest causes occasion *relapses;* and they preserve their sanity only by continuing to live where no mental agitation or inquietude is likely to befall them, and throw them back into their former state.

203. *a.* A *relapse* may be said to occur, when the malady returns, whilst the patient has scarcely, or very recently, recovered, or when he is only in a state of convalescence. It may take place a few weeks, or two or three months, after an attack of insanity. The precise time, Dr. Burrows remarks, when a cure may be said to be complete, is assigned with difficulty. Many experience, for weeks, even months, after recovery, uneasy sensations or confusion in the head; and, as long as these are complained of, no confidence can be placed in the stability of the cure. But when these sensations entirely cease, and all the functions are restored, any subsequent access of insanity is, as in other maladies, a *recurrence* of it, and no relapse.

204. Men are said to be less subject to relapses than women; but this is not the case, for numerous circumstances influence the chance of this event taking place, and to most of those men are more exposed than women. As soon as convalescence commences, the care of the physician and attendants is especially required; for, if imprudent measures be adopted before this period has been succeeded by restored health, a relapse will probably be thereby occasioned. The middle and poorer classes are more apt to relapse than the rich; for the former go from an asylum direct to their misery, and to encounter the exciting causes — probably the same causes which produced their derangement; whilst the latter may enjoy intermediate measures of precaution. Most of the relapses, as well as recurrences, of the disease, proceed from a premature or incautious gratification of habits and indulgences concerned in the production of the primary attack, or from too great mental exertion for the weakened state of the faculties, or from mental excitements or contrarieties.

205. *b.* The probability of a relapse is generally in a ratio with the suddenness of recovery, and is most frequent in mania. Recurrences are most common in melancholia; and, as well as relapses, are very apt to occur, when the mind is influenced by religious fears. Relapses or recurrences are announced by nearly the same symptoms as preceded the first seizure; and when warning has been taken by these, and medical aid procured, a return of the malady is frequently prevented. Indeed, it should always be remembered, that, when the mind has been once disordered, a predisposition is thereby created to a return of the malady when subjected to any of the exciting causes. In some constitutions, this predisposition or aptitude to a renewal of the complaint is much stronger, than in others; and to its greater strength in some persons, is partly to be attributed the remittent or intermittent character it frequently assumes; and the periodicity which it often observes, and which is probably owing to an increase of the predisposition by various physical influences recurring at stated periods. Each successive attack increases the morbid tendency to a return of the malady, and shortens the interval between it and that which is to follow; until, at length, the

intervals not only become much shorter, but also more imperfect; and the disorder at last assumes a remittent, or a permanent form.

206. *c.* The *proportion of cases* in which insanity is recurrent, has been generally overrated, in the opinion of Dr. PRICHARD. Of 444 recoveries, M. PINEL reckoned 71 cases of relapse and recurrence: but, of these 71 cases, 20 patients had experienced several attacks; 16 had left the hospital too soon; 10 came afterwards under treatment, and recovered without relapse; 14 had given themselves up to grief and intemperance; and several others were unfavourably circumstanced. M. ESQUIROL reports 292 recurrences of insanity out of 2804 recoveries, or a little more than one tenth. M. DESPORTES states, that 52 recurrent cases were recognised at the Bicêtre, in 1821, out of 311 admissions; or 17 in 100: and that 66 were received at the Salpêtrière, out of 454 admissions; or 15 in 100. M. GEORGET, however, remarks, that there were, amongst these cases of relapse and recurrence, many who had been discharged in a state of incomplete recovery, as well as a number of drunkards who came every year to spend some weeks in these hospitals, having been taken there in a state of intoxication.

207. Mr. HITCH has furnished Dr. PRICHARD with the particulars of 68 re-admissions, from among 546 admissions. These 68 re-admissions occurred in 25 persons only; and of these, there were 17 men, 10 of whom were paupers, re-admitted forty-nine times; and 8 women, of whom 4 were paupers, who were received nineteen times. Many of those who were re-admitted, had been either removed uncured by the wishes of friends, or discharged "relieved on trial," their friends having found it necessary to replace them: some returned after an apparently perfect cure. The general inference at which Dr. PRICHARD has arrived, is manifestly correct, that the improbability of a recurrence of insanity increases with the length of time which has elapsed without any sign of renewed disease; and that it is also greater in proportion to the completeness of the recovery. When the energy of the mental faculties is fully restored, relapse and recurrence are much less to be feared than when they remain weak and excitable.

208. iii. OF THE FATAL TERMINATION OF INSANITY. — Although the state of the brain connected with insanity may be incompatible with the due exercise of the mental manifestations, yet it may not so disturb the physical functions, as very materially to shorten or endanger life. This is shown both by the duration of insanity in many cases, and by the longevity of lunatics. Instances are adduced by M. DESPORTES and others, of the long continuance of this malady. Among the lunatics at Bicêtre, in 1822, 1 had been there fifty-six years; 3, upwards of forty years; 21, more than thirty years; 50, upwards of twenty years; 157, more than ten years. Among those in the Salpêtrière, there were 7 cases upwards of fifty years; 11, from fifty to sixty; and 17, from forty to fifty. Although many live thus long in a state of insanity, yet the mean duration of existence is shortened by it, and chiefly owing to the following causes, each of which requires a brief consideration:— 1. By exhaustion of organic, nervous, or vital energy; — 2. By the progress of the morbid state of the brain, associated with the mental disorder, so as seriously to disturb the physical functions; — 3. By favouring the development of diseases of several vital organs; — and, 4. By the occurrence of accidental disorders which may be masked by the mental disease, or concealed by it, until it assumes a serious form. The mental disorder, however, is often *symptomatic*, or sympathetic — a consequence of disease more or less latent, of some important abdominal or thoracic viscus, yet seriously affecting the constitution and nervous power; the physical malady being sometimes aggravated, and occasionally suspended for a time, by the sympathetic mental affection, but, nevertheless, terminating life sooner or later. This topic will be more particularly noticed hereafter.

209. *a. Exhaustion and depression of nervous or vital energy may proceed so far as to fatally terminate the insane state.* —This occurs chiefly in mania, wherein the inordinate excitement of the feelings, the constant agitation of both mind and body, the febrile disturbance of the system, and the continued want of rest and sleep, combine to exhaust the powers of life, and to occasion nervous depression and emaciation. In the majority of cases, the exhaustion either takes place gradually, or does not proceed so far as to endanger life; and the maniacal state passes either into recovery, or into dementia: sometimes, however, it is so extreme, or so complete, that the patient never afterwards rallies, but rapidly sinks to death. This occurs most frequently during the first two years from the commencement of the malady; and hence the greater number of deaths from mania, at this, than at any subsequent period. That this result should often follow, in cases where the excitement and general perturbation are great relatively to the amount of vital power, may be assumed *à priori*; and it is in these cases especially, that we find the organic lesions insufficient to account either for the mental disorder, or for the fatal termination. In extreme cases of melancholia, death may take place from depression, or sinking of nervous and cerebral power; and this state may be aggravated even to a fatal issue by a too depressing or exhausting method of cure, or from want of those means of restoration required by the peculiarities or exigencies of the case.

210. *b. The morbid state of the brain associated with the mental disorder may proceed so far as to seriously, and at last fatally, disturb the physical functions.* — In these cases, the lesions of the brain may vary remarkably in respect of seat, extent, and nature of parts implicated in them; and may commence gradually, and proceed slowly to fatal disorganisation, or may take place more or less suddenly, and terminate rapidly. In either case, we can observe only the ultimate and gross results in our examinations of the brain and its appendages after death; but there can be no doubt that these, during their development and increase, give rise to phenomena, several of which have been described when treating of the principal *complications* of insanity (§ 167. *et seq.*), — especially to the different forms of paralysis, to epilepsy and convulsions, to apoplexy, and to coma, either of which may terminate life.

211. *c. The development of serious diseases of vital organs seated in either the thoracic or the abdominal cavity, and even of the system generally, seems to be favoured by insanity*; and it is to these

diseases that a fatal termination is often owing. Many consider the occurrence of these diseases accidental; but they are so frequently observed among the insane, relatively to other classes of persons, that something more than chance is concerned in their production. As I believe that insanity — and particularly certain forms of it — is more or less connected with general debility of the organic nervous system, expressed more especially in the brain; so I consider that the functions, and subsequently the structure, of other important organs will suffer during the continuance of it, — particularly if any predisposition to disorder in these organs have already existed. And, accordingly, we find that those viscera most obnoxious to disease, especially in weakened states of vital energy, are the most frequently attacked. — *a.* Most writers and observing practitioners have remarked the great number of instances in which the death of insane persons was owing to *tubercular consumption* and inflammations of the pleura. In these cases, the pulmonary disease has generally proceeded in an insidious or latent form, until shortly before the fatal event has taken place. In many, insanity may be viewed as inducing a disposition to disease of the lungs, and as favouring the operation of its exciting causes, which may be more than usually influential and frequent in their operation during mental disorder. Dr. GREDING found that 40 out of 100 maniacs, and 20 out of 25 melancholics, laboured under phthisis; and that 74 of 100 maniacs, and 20 out of 24 melancholics, were found to have more or less effusion, either in one or both cavities of the thorax. This may be an extreme frequency of these complications, or be owing to local or peculiar causes; but there can be no doubt of their frequency. Insane persons affected by these diseases of the lungs, lose their strength, suffer slow or hectic fever, become emaciated, and at last have cough and shortness of breathing, with diarrhœa. In this state the insane symptoms rather increase than abate, and generally continue until death. In some cases, the pulmonary disorder precedes the mental disorder, or accompanies it. This is especially the case with melancholia, as remarked by M. ESQUIROL, and with hypochondriacal monomania. In these, the impairment of vital power affects both the lungs and the functions of the brain, and sometimes both nearly simultaneously.

212. *β. Diseases of the heart* and great vessels are also often concerned in hastening a fatal issue of insanity. M. FOVILLE states, that five out of six bodies display, upon examination after death, some organic disease of the heart and great vessels, — particularly hypertrophy of the heart. This is most probably owing, in part, as he supposes, to the violent efforts and agitation of insane patients.

213. *γ.* Although *diseases of the digestive organs* frequently exist previously to the appearance of insanity, and are often more or less concerned in causing it, yet they often do not become objects of attention until after it has fully declared itself; when, from their nature or severity, they obtrude themselves upon the notice. Whether the disorder consist of gastro-intestinal irritation or not, at the commencement, it frequently passes into it; and, at last, terminates in ulceration, originating chiefly in the mucous follicles, or in abrasion of portions of the mucous membrane. At the beginning of the mental disorder, and particularly of melancholia and mania, constipation is both obstinate and of long continuance; the most drastic or active medicines being required to act upon the bowels. But it generally at last gives way, and is followed by, or alternates with, diarrhœa, which sometimes passes into dysentery, and which rapidly exhausts the strength of the patient, without abating the mental disorder.

214. *δ.* The *cachexia* already noticed, frequently associates itself with other maladies, in causing a fatal termination of insanity, and particularly with disease of the alimentary canal, and enlargement, obstruction, torpor, and congestion of the *liver*, and even also of the *spleen*. In many cases, this state of cachexia is evinced by a sallow, lurid, dirty, and scaly state of the skin; and by papular eruptions or discoloured patches. It sometimes proceeds to more obvious disease of the fluids and soft solids; furunculi and carbuncles break out in different parts of the body, and sometimes slough extensively; the gums become spongy and sore, and bleed upon the slightest irritation; livid blotches occasionally appear on the lower extremities; and complete scurvy at last supervenes. In other cases, emaciation, occasionally amounting to marasmus, a cold and clammy state of the general surface, diarrhœa, and colicky pains in the abdomen, take place, either with or without the more obvious indications of scurvy; and the patient sinks from the gradual decay of vital power, and the effects of this decay upon the digestive, the assimilative, and nutritive functions. These cases are most frequently met with in dementia and chronic mania, — the mental faculties indicating a failure of the vital manifestations of the brain, altogether similar to that of the other important organs of the body.

215. *d. There are other maladies of more accidental occurrence, which often terminate the life of the lunatic.* — These, as well as the most of those just noticed, may be masked by the mental disease, or entirely concealed by it, until they reach a serious or even dangerous form, or they may not be detected until disclosed by a *post mortem* examination. The complaints of the patient even are often overlooked and taken for delusions. This is especially the case in hypochondriacal monomania, and melancholia. But the truly observing physician will frequently recognise, in the delusions of the insane, bodily disease of a serious nature. Several of the delusions already noticed, have been shown to depend upon contingent organic lesion of a vital or important organ. Sufficient proofs of the truth of this have been adduced above (§ 21.); and I need not further allude to this topic, than to press the importance of this connection, and the necessity for carefully ascertaining what connection may exist between the illusion entertained and visceral lesion. Many of the diseases which may be viewed as accidental only as respects their occurrence in lunatics, may, in some degree, be owing to the physical state of these individuals; inasmuch as they are more frequently attacked by these diseases, and suffer more severely from them than any other class of persons. — Fevers and chronic inflammations are often met with among them; the former generally assuming a typhoid character with predominant cerebral affection, and frequently terminating fatally; the latter often giving rise to effusion, and causing death in consequence.

216. *e.* The *diagnosis of visceral diseases in lunatics* is remarkably difficult, owing either to the unfounded complaints made by them under the influence of fancied and erroneous sensations, or to the extent to which the mental disorder masks the physical disturbance. Many lunatics labour under severe diseases, without evincing them by any expression — because either these diseases do not occasion much suffering, or the disturbed state of their minds prevents the morbid sensation from being perceived. In this latter respect, the diseases of lunatics are more obscure than those of infants, because the latter express their ailments by their cries and attitudes. M. GEORGET justly remarks, that, where we observe a lunatic, who had previously been agitated and furious, become morose and taciturn, and at the same time lose his appetite, seek repose, and display a suffering and dejected expression, we ought to examine him carefully, for he is attacked with acute disease. The development of symptoms will soon point out the seat and nature of the malady. But chronic affections are so slow in their approach, and so latent in respect of their symptoms, that they often reach a very advanced stage before their existence is suspected, unless a careful examination had been made before, as well as after, their commencement. This is especially the case in regard of diseases of the lungs, heart, pleura, and of the organs of digestion. From this it is manifest that insane persons should be carefully watched and examined, and that the states of the lungs and heart should be investigated from time to time by percussion and auscultation.

217. *f.* The *rates of mortality* among lunatics have received much attention from M. ESQUIROL and Mr. FARR; the former of whom states, that the highest rate, for the two sexes, is between the ages of 40 and 50: that of women is greatest between 50 and 60; that of men between 40 and 50. A greater number of men than women die insane; and this is partly owing to the greater frequency of the more dangerous complications in the former than in the latter. M. ESQUIROL concludes, from a comparison of different hospitals, the deaths to be — in *mania*, 1 in 25; in *monomania*, 1 in 16; in *melancholia*, 1 in 12; and in *dementia*, 1 in 3. He further states, that a greater number of deaths take place in December, January, and February, than in any other three months. Mr. FARR states, that the mortality furnished by Bethlem, St. Luke's, and the Asylums at Stafford, York, Lincoln, Gloucester, and Hanwell, amounted to 10·40 out of 100 treated; that the annual mortality among lunatics was 9 per cent.; and that the mean ages of those admitted at Bethlem varied from 36 to 39. That no precise idea can be formed, however, from these data, of the mortality of the insane, is evident from the fact, that two of the principal of these institutions do not admit any but recent cases, and that they do not allow these cases to remain longer than one year. Enough, notwithstanding, is adduced to prove that *insanity remarkably shortens the mean duration of life.*

218. Considerable difference exists in estimates formed by writers of the numbers of deaths from the prevailing diseases among lunatics. Indeed, no precise data can be furnished on this point; for those who parade numerical data or details in this, as well as in other maladies, by no means satisfy us in what manner those details have been obtained. Numerical results, unless furnished by the ablest and most discriminating observers, and with the utmost accuracy and good faith, may mislead more than instruct: and this is a subject on which it is next to impossible to furnish them with precision. Besides, the comparative prevalence of fatal diseases in lunatics will necessarily vary in different places, with numerous related circumstances and contingencies. The diseases, also, of the insane are often so complicated, that different observers may impute the fatal result to different affections or lesions even in the same cases, although the matter may seem to have been placed beyond dispute by a *post mortem* examination. Thus, tubercular formations in the lungs and extensive ulcerations in the bowels will often be found in the same case; or disease of the liver, lesions in the brain, and inflammation of the peritoneum, or of the pleura, in another; or changes in the heart, effusions into the cavities, and lesions of some other organ, in a third: and hence different physicians may ascribe death to very distinct organic changes. Some, even, satisfied with the alterations presented by one vital organ, may leave other important viscera either entirely unexplored, or insufficiently investigated, although they may be equally, or even more, affected.

219. Notwithstanding these objections, it may be conceded that the most fatal maladies among the insane occur nearly in the following order as to frequency: — More or less sudden deaths from apoplexy, coma, and convulsions; — pulmonary and pleuritic lesions; — nervous, typhoid, adynamic, and putro-adynamic fevers, usually with predominant affection of the brain; — general palsy; — general cachexia, frequently with colliquative diarrhœa; — organic lesions of the liver, bowels, and mesenteric glands, causing marasmus, &c.; — exhaustion of vital power without sufficient alteration of structure to account for death; — structural change of the heart, &c.; and dropsical effusions into shut cavities, particularly the pleural and pericardiac; — mortification, chiefly of parts pressed upon, and of the extremities; — organic changes in the stomach and pylorus; — chronic peritonitis, generally latent; — alterations of the uterus, spleen, and pancreas, &c. Organic lesions of the brain, lungs, heart, and digestive organs are found variously associated, in most cases, upon examination after death; those of one organ predominating over the rest in different cases, and seldom presenting a due relation to the symptoms or disorders complained of, or manifested during life. Diseases in the abdominal organs, and particularly in the intestinal mucous surface, are amongst the most frequent morbid associations of insanity, but generally contingent upon it, and not until an advanced period of its progress; although, as will appear in the sequel, they are also important physical causes of it. M. ESQUIROL observes, that of upwards of 600 examinations after death, three eighths die of diseases of the abdomen, two eighths of diseases of the chest, and three eighths of alterations of the brain and membranes. The proportion here assigned to the first class of diseases is probably too high, and especially in respect of this country. A very able writer remarks, that the reports of lunatic asylums partly show, that the corporeal ailments, under which the patients languish and die, are very often overlooked, and are

consequently not met by proper treatment; and that these establishments are made a kind of show-houses, instead of being hospitals for the complicated diseases which involve the functions of the mind. "We grant," he goes on to state, "that the mental malady may often be but the first sign of that total impairment of the frame which phthisis, or hydrothorax, or scorbutus, or paralysis, or marasmus afterwards more plainly declare; but we suspect there are cases in which, if the life of the patient were preserved through some of the maladies supervening on the mental disorder, the mind would be found to be restored, and the malady to be critical. With the present management of lunatic hospitals, these conjectures can neither be verified nor refuted. In many of them, medical aid is considered to be nearly superfluous; and in some, we are informed that the appointment of physicians in ordinary has been, if not rejected by the governors, at least, subjected to grave debate, as if the County Asylum were no more than a supplementary county jail." (*Brit. and For. Med. Rev.* No. xiii. p. 30.).

220. M. ESQUIROL gives the following tables of the mortality in insanity, according to the ages:—

	BICÊTRE. No. of *Men* admitted from 1784 to 1794, 2405.	SALPÊTRIÈRE. No. of *Women* admitted from 1804 to 1814, 2804.
20 to 30	25	58
30 to 40	176	83
40 to 50	215	143
50 to 60	134	173
60 to 70	90	123
70 and upwards	45	210
	685	790

Table of the Mortality at the Sâlpetrière during 10 Years.

No. admitted each Year.	1804	1805	1806	1807	1808	1809	1810	1811	1812	1813	Total.

2804											738
Deaths during this period amongst those admitted before 1804											52
											790

Of 790 deaths at the Salpêtrière, from 1804 to 1814, 382 occurred in the first year after admission, 227 in the second, and 181 in the seven following years.

221. The table of deaths from insanity, and from the diseases of the brain most nearly allied to insanity (p. 475.), is made up from the "*Abstracts of the Causes of Deaths registered in England and Wales, from 1st of July to 31st of December, 1837, both inclusive.*" These abstracts, and the remarks accompanying them, by Mr. FARR, are extremely valuable to medical men. It is to be hoped, that the reports of the register general will appear annually. Mr. FARR states, that the insane, who die in lunatic asylums, have often been registered improperly under secondary diseases, such as apoplexy and diarrhœa. Under the head of violent deaths are included suicides, accidents, &c.; and it cannot be doubted, that the great majority, at least, if not the whole, of suicides, are instances of some form or grade or other of insanity.

222. V. OF THE ALTERATIONS OF STRUCTURE CONNECTED WITH INSANITY. — It is evident, even from what I have already stated, that few diseases are connected with so great a diversity of structural changes as insanity; and there is none which has given rise to so much discussion and difference of opinion as to the nature of this connection, as it has occasioned. It has even attached to itself a very particular interest at present, owing partly to its importance, and partly to the very opposite views entertained respecting it by some of the most experienced of recent writers on mental diseases. — But little information was furnished on this subject previously to the almost contemporaneous publication of some cases, with the *post mortem* appearances, by MORGAGNI and MECKEL. — BALLONIUS, and long afterwards BONET, had furnished a few particulars; but these were rather of lesions found in the thorax and abdomen, than of changes within the head; and it was not until the investigations of GREDING, MARSHALL, and HASLAM appeared, that the appearances of the brain in fatal cases of insanity received any degree of attention. More recently, the researches of PINEL, ESQUIROL, GEORGET, BAYLE, LALLEMAND, BOUILLAUD, NEUMANN, GUISLAIN, CALMEIL, and FOVILLE, have been most assiduously directed to this interesting subject; still the results furnished by them are of such a kind as to prove the necessity for further investigation, carried on independently of preconceived opinions. Although British writers have hitherto contributed but little to this department of medical knowledge, it is to be hoped that those who have the management of public institutions for insanity in their hands, will see the advantages which will result contingently even to those connected with themselves,—will catch a glance of their own interests prospectively,—from the encouragement of researches into the pathology and treatment of the most distressing of all maladies, not merely for the benefit of the few subjects of the maladies to whom they are guardians for a time, but also for the instruction of those to whom the community have to look for aid in these calamities, and, consequently, for the advantage of all classes in society.

223. i. MORBID APPEARANCES OBSERVED IN THE HEAD. — *A.* The *cranium* seldom presents any change from the healthy *shape*, excepting in epileptic or idiotic lunatics. GREDING states, that of 220, only 16 had the forehead contracted, the temples compressed, and the occiput large and expanded. In a few, the head was elongated and compressed laterally. In some, the head was almost round, or of a square shape: these were chiefly epileptic lunatics and idiots. I have observed, in this class, one side of the head higher than the other, and sometimes also more prominent, whilst the other side receded, giving rise to the *diamond-formed obliquity* or deformity of the skull described by me in the article CRANIUM (§ 9.). Of 26 cases, including epileptic lunatics and idiots, GREDING observed 2 belonging to these latter, with very small and quite circular heads. Of the whole number of cases (220), the skull was unusually thick in 167: this was

observed in 78 out of 100 cases of mania, and in 22 out of 30 idiots. In some cases, the cranium was remarkably thin. Numerous foramina were observed in the inner table of 115 out of 216 cases; and, in some instances, bony projections arose from this table. Similar changes in the cranial bones were noticed by Neumann and Georget, — the latter of whom has inferred hypertrophy of these bones to be still more frequent in lunatics than stated by Greding. The bones of the head have likewise been observed more vascular than natural by Calmeil and others. (See art. Cranium, § 9—12.)

224. *B.* The *membranes of the brain* are frequently altered. — *a.* Greding found the *dura mater* adherent to the cranium in 107 out of 216 cases; in a few instances, of a bluish black colour, thickened, and containing ossific deposits. Similar lesions were observed by M. Georget, who also detected the *arachnoid* sometimes thickened, but smooth, and occasionally presenting, in places, additional lamina of a red or grey colour. The *pia mater* was, according to this pathologist, injected, thickened, and infiltrated with serum, giving it at first the appearance of a gelatinous deposit. Greding found it thickened and opaque in 86 out of 100 cases of mania, and beset with small spongy bodies in 92 out of 100; these bodies being united to the surface of the brain, and in some instances containing ossific matter. M. Calmeil has described these excrescences, granulations, or spongy bodies, to arise or grow from the pia mater so as sometimes to penetrate the dura mater and cause absorption of the inner bony surface of the cranium: and he has remarked, that infiltrations and thickenings of parts are almost constantly found under these excrescences. The above changes in the membranes, and particularly in the arachnoid, have been recorded also by Haslam, by Guislain, and by M. Bayle. To these alterations, and to effusion of serum between the membranes and in the ventricles, this latter physician ascribes the chief phenomena characterising and contingent upon insanity.

225. *b. Effusions of serum* between the dura and pia mater were observed by Greding in 120 out of 216 cases of insanity, and in 58 out of 100 maniacs; and between the pia mater and surface of the brain, in 28 out of 100 cases of mania. The lateral ventricles were full of serum in 29 instances, and remarkably distended in 23. They were equally distended in 10 amongst 24 cases of melancholia. The third ventricle was quite full in 57 out of 100 maniacs, and in 16 out of 24 melancholics. The fourth ventricle was distended to the utmost in 80 out of 100 maniacs, and quite empty only in 3. It was greatly distended in every one of 24 melancholics examined. Dr. Haslam found serum effused between the membranes in 16, and in the lateral ventricles in 18, out of 37 cases. Effusions between the membranes and in the ventricles were met with also by MM. Georget, Guislain, and Bayle, — the last of whom ascribes insanity to inflammatory irritation of the membranes; effusion following upon the inflammation, in his opinion, and occasioning the cessation or diminution of maniacal violence, the great loss of power in the intellectual faculties, and the commencement of general paralysis, owing to the pressure caused by the effusion. According to this view, the progress of dementia, fatuity, and general paralysis indicates a corresponding increase of effusion and of pressure on the brain. Other writers, who differ from M. Bayle as to the origin and seat of insanity and general paralysis in chronic inflammation of the membranes, and of serous effusion from them, readily admit the great frequency of these lesions. Lallemand, Calmeil, Bouillaud, Casauvieilh, and Foville have all described similar changes to the above; but have viewed them more in connection with alterations in other parts, and estimated them differently.

226. *c.* The *choroid plexus* was found in a healthy state by Greding in 16 cases only out of 216, and thickened and full of hydatids in 96 out of 100 maniacs. M. Georget has remarked that the choroid plexus was exsanguineous, and contained hydatidiform vesicles.—The *lateral ventricles* were in some instances very small; but, much more frequently, large, and distended, as just stated, with serum, which was remarkably clear and limpid. — The *convolutions* of the brain were often observed, by M. Georget, separated by an effusion of serum, and the pia mater thickened.

227. *d.* M. Foville states, that, in acute cases, the morbid appearances discovered in the meninges were chiefly injection of the pia mater; and that this injection was generally proportioned to the degree of inflammation existing in the cortical substance of the convolutions. The small arteries and veins passing from the membrane and penetrating the grey matter were distended with blood: the arachnoid, in these cases, generally retains its natural aspect. The chronic changes in the membranes, according to this observer, consist for the most part in opacity, increased consistence, thickness of the arachnoid, the formation of granulations and false membranes on its surface, and the effusion of serum into the cellular tissue of the pia mater and into the ventricles. The arachnoid is often, in patches or more extensively, of a pearly whiteness. The opacity of this membrane is always attended by thickening; and in the place where the arachnoid and pia mater are naturally contiguous, they are found to be adherent. The opaque patches result from the deposition of albumen upon the arachnoid.

228. *C.* The *substance of the brain* has been more closely examined in cases of insanity, in recent times, than heretofore. Indeed, the progress that has lately been made in the minute anatomy of this organ, will necessarily enable the pathologist to recognise many lesions of its structure, which were entirely overlooked in former times. The researches of M. Foville into the state of the brain in persons who have died insane, are of great importance, and were carried on by him in the Sâlpetrière, aided by MM. Delaye and Pinel Grandchamp, and subsequently in the extensive hospital of St. Yon, near Rouen, which is under his care. The morbid appearances which I proceed to describe, as having been observed in the brain, are chiefly the results of his investigations.

229. *a.* The *grey substance of the brain* presents, in the most acute cases, on the removal of the membranes, intense redness of its surface, approaching to that of erysipelas. This is still more marked in the substance of the cineritious tissue itself; and it is more striking in the frontal region, than in the temporal and lateral lobes,—and in the higher regions, than in the posterior parts. — In *acute cases* of insanity, M. Foville states that

the changes in the grey matter consist of uniform and intense redness of colour, with numerous mottled spots, varying from a bright to a violet red, and bloody points or minute extravasations of blood; of diminished consistence of this structure, coincident mostly with a slightly increased consistence of its surface; and of dilatation or enlargement of its vessels. He has never observed, in these acute cases, adhesions of the membranes to the cortical substance, which are very frequent in chronic cases. To this circumstance he ascribes the curability of recent cases, and the incurability of dementia, and chronic cases.

230. In these latter cases, the grey or cortical substance becomes much firmer, and dense, in the superficial part; and this part, owing to its uniformity, constitutes a distinct lamina, smooth externally, but irregular internally; of a lighter colour than usual; and admitting of being torn or peeled off, leaving the remainder of the grey substance red, soft, and mammillated. Sometimes this pale and dense surface, or part of the cortical substance, is rough and granulated, containing small grains of a yellowish white. In conjunction with these, the volume of the convolutions remains natural, or is lessened or atrophied. When it is the latter, linear depressions or irregular pittings exist on the surface of the convolutions; and in the grey substance itself, small yellowish lacunæ, filled with a yellowish serum, are found. These lacunæ are supposed to correspond with, or to be the remains of, the minute extravasations observed in acute cases. In other instances, the diminution of volume is a real atrophy of the convolutions, which appear thin and angular, as if pinched up towards their extremities. This change is very frequent in the frontal regions of the hemispheres, and often particularly comprises three or four convolutions in each side of the sagittal suture, — a chasm, filled with serum, occupying the place left by the absorbed substance. Coexistent with this alteration, is often observed a limited atrophy of the cranium, or a circumscribed disappearance of the diploë, owing to which the external table approaches the inner, leaving a superficial depression. In this atrophy of the convolutions, the diminution of substance is confined frequently to the cortical or grey matter; what remains of it being harder than natural, and sometimes presenting, on close examination, a fibrous structure. It is also of a darker colour, and occasionally seems separable into layers, — the exterior being pale, and the interior of a rose colour.

231. Softening of the grey substance is also often observed, in chronic cases of insanity, extending through its whole thickness, and not superficial merely. This softening is generally attended by a greater depth of colour, which often approaches to brown, and is frequently so great as to amount almost to liquefaction of this structure. This extreme and general softening of the cortical substance is not necessarily attended by a similar change of the white structure; but is sometimes conjoined with a hardened state of that structure. In these cases, the grey may be separated from the white substance by the effusion of water. These more extreme alterations are found, especially in the worst cases of dementia, complicated with paralysis and marasmus. MM. FOVILLE and CALMEIL have met with instances of this description, in which limited portions of the grey substance had disappeared previously to death. The grey structure in other parts of the brain does not present the same changes as have now been described as taking place in the convolutions; but generally exhibits alterations similar to those of the medullary or white substance. The cortical structure, however, of the cornu ammonis is in some cases softened, and in others hardened.

232. *b.* The *white or fibrous structure of the brain* is often found altered in colour, density, and texture. It is frequently injected, and its vessels more or less enlarged, exhibiting numerous bloody points on sections of it. In other cases, it has a mottled appearance, of a deep red or violet hue, owing, as M. FOVILLE believes, to a finer injection of its vessels, as shown by the magnifying glass. These injections of the white structure do not always coincide with similar injections of the grey substance. Sometimes the fibrous or white structure is splendidly white; and generally at the same time increased in density, or hardened. This induration occasionally amounts to an almost fibro-cartilaginous state. In two or three cases, I have observed the increase of density nearly to resemble the white kind of caoutchouc. The hardened fibrous structure, however, may not be remarkably white; it is sometimes of a yellowish, or of a greyish or leaden, tinge. M. FOVILLE accounts for the induration of this structure, by supposing that the cerebral fibres have contracted adhesions to each other, so as to render their separation impossible. According to him, the fibrous mass of the hemispheres consists of several distinct layers or planes of fibres applied one upon the other, and connected by very fine cellular tissue. These planes are easily separable in the healthy state, but become inseparable in the course of mania. The occurrence of tubercles and tumours in the brain is considered by him as accidental, when met with in cases of insanity.

233. *c.* The *cerebellum* undergoes alterations similar to those observed in the brain, but much more rarely.

234. *d.* The *nerves* sometimes present changes corresponding with disorders of sensation and perception. M. FOVILLE has found the optic nerves hardened, and otherwise altered, in persons troubled with hallucinations of sight.

235. *e.* The *morbid appearances found in cases of insanity complicated with general paralysis* have especially engaged the attention of M. CALMEIL. In this association of mental and of physical disease, it is very difficult to determine, as Dr. PRICHARD remarks, what alterations are connected with either morbid state; and certainly many of the changes met with by M. CALMEIL, in these paralytic cases, are similar to those regarded by various writers as connected with insanity, without reference to its association with paralysis. This pathologist concludes that general paralysis is not dependent upon compression of the brain by serous effusion, as supposed by M. BAYLE, but upon the disease of the encephalon which gives rise to the effusion, and chiefly on inflammation, of which the thickenings, and lesions, and vascular turgescence of the pia mater, and the peculiar condition of the grey structure, afford sufficient evidence. M. CALMEIL has succinctly enumerated the changes observed by him in the encephalon, in this class of complicated cases, nearly as follows: — Injection and absorption of the bony structure; injections of the

dura mater, separation of its fibres; effusion of serum into the cavity of the arachnoid; false membranes, organised or without organisation; cysts filled with blood in its two laminæ; simple hæmorrhages in the arachnoid; œdema of the meninges; injections and thickenings of the membranes; vegetations of the pia mater, and development of its vessels; adhesions between the pia mater and the convolutions; disappearance of the grey substance; softening, induration, and discolouration of this substance; hardening and injection of the white or fibrous structure; redness and tumefaction of the ventricular villosities; serous effusion into the ventricles; apoplectic cysts; erosions of the convolutions; softening of the brain, or of the spinal marrow. These changes are so various, and so far from uniform in occurrence, that they cannot satisfactorily explain the results imputed to them. M. Calmeil considers them all to be proofs of a chronic inflammation of the brain; and in this, as well as in his descriptions of many of the alterations, he agrees with M. Foville. This latter writer states that, in lunatics affected with general paralysis, he found the induration of the fibrous structure of the hemispheresd escribed above (§ 232.), wanting only in two cases, and in these the cerebral nerves, the annular protuberance, and the medulla oblongata presented extreme hardness. He states further, that this induration of the fibrous structure of the brain has been found in old men, whose voluntary movements have become uncertain or vacillating; but it has never been seen in lunatics whose muscular powers had remained unimpaired. I have observed induration of the spinal cord, with effusion of serum between the membranes, and other changes, in two cases of general incomplete paralysis unattended by insanity; both patients, however, having become delirious shortly before death.

236. The brain has occasionally been so infiltrated with serum, that the fluid has flowed from the surface of the incisions. This infiltration has been so remarkable in a few instances, as to constitute a true œdema of the brain. Much more rarely, as observed both by Esquirol and by myself, a multitude of pores or small cavities, containing a limpid serum, have been found in the substance of the brain; a section of the part thus changed resembling that of a porous cheese. In these cases, the brain may be also somewhat indurated and changed in colour. It is by no means determined, as some suppose, that these pores or cavities are the sequelæ of vascular extravasations. It is more probable that they are the consequences of softening; the pores being left by the removal of the molecules of the cerebral substance, which have lost their vital cohesion to the rest of the structure, and filled by a serous effusion.

237. *f.* The *inferences which may be drawn from these researches* deserve a brief notice. It will be seen from these, that M. Foville ascribes the morbid appearances to inflammation; and, in this, agrees with Calmeil and others. But it will be remarked by many, and not the less by those who may have read the article Inflammation in this work, that this term has been applied, and possibly is applicable, to several lesions, attended by changes in the state of capillary and vascular action, each differing more or less from the other, and accompanied with different, or even opposite, conditions of organic nervous or vital power; and that, although these lesions may be apparently quite similar, and be followed by nearly the same results, in different cases or persons, yet may the state of vital power or manifestation, in respect not only of the functions of the brain, but also of the whole economy, differ remarkably in each particular instance. It is well known that the lesions constituting, as well as consequent upon, several kinds of phlegmasiæ — upon phlogosis, or simple sthenic inflammation, and upon erysipelas and other forms of spreading or asthenic phlegmasia — nearly resemble each other; but they are attended by very different constitutional disorder; and this is independently of grades of activity or intensity of action. Besides, something should be attributed, in many cases, to the influence of the moral causes, and to the consequent mental excitement, upon the cerebral circulation, with reference not only to prolonged erethism or excitement of the capillaries distributed to the organ of mind, but also to constitutional or vital power, and to the various maladies of which the cerebral affection may be only a symptom, or sympathetic disorder. We know that, in other organs or parts, a prolonged irritation or excitement of their capillaries, by agents which excite chiefly the nerves supplying them, will so determine the blood to them, and so enlarge and develop their vessels, as to give rise to appearances which nearly resemble the consequences of inflammation. We find, moreover, that the most violent forms of mania and of delirium, and the most fatal when not judiciously treated, are actually those in which inflammatory appearances are the least evinced, or in which states opposite to inflammatory really exist. We find, also, lesions in the brain — whether inflammatory or not — equally extensive with those observed in the most general and complicated cases of insanity, and without any disorder of mind having existed during life. Can we, therefore, legitimately impute insanity, in all cases, to these lesions? or may not these lesions be just as legitimately imputed to the insanity? There is very probably a connection between them, in most cases; but neither the exact nature of the connection, nor the intimate relations and source of the morbid alterations observed, have been yet fully ascertained. This is, however, no reason wherefore we should altogether reject the conclusions at which able and experienced observers have arrived, until we obtain others upon which more implicit reliance can be placed.

238. The morbid changes in the encephalon, M. Foville infers to be the results of inflammation: intense, diffused, and general redness; in many cases, tumefaction; and, in passing to the chronic state, the formation of adhesions between the cortical substance of the convolutions and the contiguous membrane: besides this, adhesion of the different planes, or layers of the cerebral substance, to each other, in a certain number of cases. As the different traces of inflammation are more constant in the brain than in the membranes, M. Foville concludes that the essential change connected with insanity takes place in the brain, and that alterations of the membranes are only accidentally connected with it. Amongst the morbid appearances in the brain, lesions of the grey structure are considered by him as the most constant in connection with the mental disorder. Although M. Calmeil was inclined to ascribe loss of mus-

cular power to disease of this structure, M. **Foville** contends that the facts upon which he founds this inference do not warrant this conclusion. In all the cases of general paralysis he has examined, there was, besides the change in the grey structure, some alteration, either hardening, serous infiltration, or softening, of the white or fibrous substance; and in most cases, in addition to these, there were adhesions of the principal planes of the cerebral substance to each other.

239. From the circumstance of the grey substance of the hemispheres being found in a state of disorganisation or atrophy, in cases where intellect was abolished, and the fibrous structure being natural where muscular power was unaffected, as well as from the fact of lesions or wasting of this latter structure being observed where voluntary motion was lost or affected, M. **Foville** infers, that the function of the grey structure of the brain is essentially connected with the intellectual operations, and that the office of the white or fibrous part is subservient to muscular action; and consequently, that—1st, morbid changes in the former part are directly connected with intellectual derangement; and, 2dly, those in the latter portion are connected with disorders of the motive powers. He, however, admits, that in some affections of the maniacal class succeeding the action of debilitating causes,—as in the puerperal state,—nothing has been discovered in the brain more striking than its extreme and general paleness; and that, although some mottled appearances of a light red or rose colour are met with, these changes are too slight to be considered as idiopathic. M. **Foville** is therefore induced to consider this form of mental disorder to be symptomatic of some deep-seated disease of the uterus or abdomen. But, unfortunately for his argument, of several cases of puerperal mania which I have treated, I have not met with one that did present any serious or deep-seated disease in these parts. There can be little doubt, however, that the contradictory evidence given by different observers of the appearances of the brain in cases of insanity, is partly accounted for, as remarked by an able writer, by the existence of cases in which the affection of the brain is merely functional and sympathetic,—the primary disease being in some other organ, especially in some of the abdominal viscera.

240. The evidence of those who believe that insanity, although often connected with organic lesions of the brain, especially in protracted and extreme cases, does not necessarily depend upon them, requires some notice. Here the experience of M. **Esquirol** attaches to itself great importance. He remarks, that the bodies of lunatics offer numerous varieties as to the situation, number, and kind of morbid appearances, and that the lesions of the encephalon are neither in relation to the disorders of the mind, nor to the maladies complicated with it. Some lunatics, whose mental and bodily disease indicated extensive organic lesions, have presented slight changes in the brain; while others, whose symptoms had been less severe, have been subjects of great and numerous alterations. But even in the most protracted cases of insanity, no organic changes whatever have been traced, either in the brain, or in its membranes. He goes on to state, "that pathological anatomy is yet silent as to the seat of madness, and that it has not yet been demonstrated what is the precise alteration in the encephalon which gives rise to this disease." The various states of the brain, compatible with integrity of the mental faculties, have never been satisfactorily investigated, and probably will never be accurately ascertained; and it is by no means easy to distinguish, with sufficient precision, the appearances resulting from, or belonging to, concomitant maladies, from those which belong to the mental affection. M. **Esquirol** observes, that organic lesions of the brain are declared by symptoms distinct from the mental disorder; that chronic inflammation produces compression and paralysis, and paralysis results from cerebral hæmorrhage; and that tubercles, tumours, and softening of the brain have their peculiar symptoms, which cannot be confounded with mental alienation. Moreover, the sudden and instantaneous relief experienced, in some cases of madness, is not to be forgotten; nor the fact, that every part of the brain has been found altered, suppurated, destroyed, without chronic lesion of the understanding.

241. The maniacal form of insanity is rarely fatal, owing to any lesion of the brain; but from fever, phthisis, and other associated maladies, or from sudden exhaustion of the sensibility or nervous power necessary to life. In a case which terminated in this latter manner, no lesion was observed in the brain after death; and in a young woman, accidentally killed in recent and furious mania, the brain and its membranes were likewise devoid of change. When a case is watched during life, M. **Esquirol** thinks that the period at which the organic lesion of the brain commences, may be known by the symptoms. When mania has existed long, he is of opinion that the weakness of the last days of life disposes to local inflammations. Upon the whole, he concludes, that, notwithstanding the labours of MM. **Foville**, **Calmeil**, **Bayle**, and **Guislain**, the organic reason of mental derangement is still undeclared. "Thirty years ago," he adds, "I should have written willingly on the pathological cause of insanity: I will not now attempt so difficult a labour,—such are the uncertainty and contradictions in the results of the examination of the bodies of lunatics after death up to this day. But modern researches permit us to hope for more positive, clear, and satisfactory notions." In another place, he admits, that a difference in the results of researches may arise from the greater care with which the brain is now dissected, and the slightest changes observed; and that, at earlier periods of the investigation into the pathological anatomy of insanity, an account was kept only of obvious alterations.

242. Respecting this matter, M. **Guislain** appears to steer a middle course in his more recent work on Insanity. After various details, he concludes, that, in the greatest number of organic lesions of the brain, a moral origin and functional state of disorder, without alteration of structure, first exists; and that, when such alterations are present, they consist chiefly of whatever causes pressure of the brain, as effusion of serum, or of blood, lymph, or the formation of a false membrane; or of constriction of the organ by its membranes, which, in their state of engorgement, incarcerates, or strangulates, in some respects, the hemispheres; or of softening, or other disorganisation, to an extent that is incompatible with the due exercise of the

mental manifestations. He adds, that *induration* of the brain has been often observed by him, especially in the parietes of the lateral ventricles, and in the rachidian bulb, or upper portion of the medulla oblongata: that epileptic convulsions frequently attend it; that convulsions are often also caused by organic lesions of the membranes, and of the cineritious structure, but not constantly either by these, or by induration; and that they may occur even without any visible change of tissue. He concludes, that absence of organic alterations of the brain is indicated by the full possession of muscular action and motion, and that the existence of them is evinced by lesion of muscular motion and of sensibility — that simple disorder or excitement of the mental faculties, without dementia or palsy, exists independently of softening or compression of the brain; and that dementia or extinction of the intellectual powers may depend — 1st, upon sanguineous engorgement of the brain; 2dly, upon effusion of serum between the membranes or in the ventricles; 3dly, upon extravasation of blood between the membranes or in the substance of the brain; 4thly, upon softening of this organ; 5thly, on atrophy of it; 6thly, on induration of it; and, 7thly, upon exhaustion of its vital influence.

243. ii. Alterations in the Thoracic Viscera. — *A*. The *lungs* are diseased in a very large proportion of the cases of insanity which terminate fatally. The proportion has been differently estimated by the writers already noticed. M. Georget declares that he has found organic changes in the lungs in at least three fourths of the cases which he had examined; and phthisis to have been the cause of death in more than half the lunatics in Salpètrière. He describes the pulmonary disease as always chronic, and often so obscure as not to be detected until the body is inspected. In these cases, the patient neither coughs nor expectorates, and he makes no complaint: he wastes, gets weak; looseness or constipation succeeds; he dies; — these changes take place slowly. Yet, notwithstanding the absence of cough and expectoration, excavations are found in the lungs after death. But instances of latent phthisis occur independently of insanity. When, however, both maladies are associated, the latter is more frequently sympathetic, or dependent upon the constitutional disturbance caused by the pulmonary disease, than is generally supposed; and it then sometimes does not appear until the softened and absorbed tubercular matter has contaminated the circulation, and thereby disturbed the functions of the brain. I have observed in persons predisposed to insanity, as well as in others, that, when tubercles are developed in the lungs, and when softening and ulceration follow without any communication having been made with a bronchus, the progress of the disease is generally latent. The tubercular softened matter undergoes changes during its retention; causes thickening or condensation of the parietes of the cavity containing it, even whilst the cavity continues to enlarge, and, if it be not evacuated by the bronchi, neither cough nor expectoration will be present. But the constitutional disturbance caused by the accumulated matter, as well as by the organic lesion of the part containing it, and still more by the absorption of a portion of it into the circulation, will so disturb the organic nervous functions, as to occasion, first, functional disorder, and consecutively, even organic lesion of such organs as may be most prone to disease from either an original or an acquired predisposition.

244. *B*. The *heart* is often changed in structure, in fatal cases of lunacy. Indeed, all the lesions of which this organ is susceptible, have been found in the bodies of the insane; but hypertrophy, passive dilatation, and softening, of the parietes of the cavities, seem to be the most frequent. The proportion of cases in which organic alterations of the heart have been found, has been differently estimated by writers. Romberg (Nasse's *Archiv. f. Med. Erfahr.* 1817.) believed that five out of seven bodies present lesions of this organ; and M. Foville considered that five out of six display alterations either of it or of the great vessels.

245. iii. Alterations in the Abdominal Viscera. — *A*. The *digestive mucous surface* very frequently presents evidence of inflammatory action, especially as respects certain of the consequences of this state. M. S. Pinel met with inflammatory appearances in this situation in 51 out of 269 bodies of lunatics; and of these there were only 13 of disease of the other abdominal viscera. These appearances have been also observed in a number of cases by Prost, Percival, and Guislain. — The frequency of displacements of the *colon*, first insisted upon by Esquirol, and especially with reference to melancholia, has already been attended to (§ 119.); and has been remarked also by Bergman, Müller, Annesley, and Guislain. In most of the cases described by Esquirol, the displaced colon presented none of the consequences of inflammation. In some of the instances observed by Percival and Bergman, the colon was contracted or more or less reduced in calibre through a great part of its length; in others, it was in parts dilated and contracted, as well as displaced. M. Guislain attributes both the displacement and the contractions to inflammatory action; — the latter most probably arises from this cause; but the former cannot always thus be accounted for. From the few instances which I have had an opportunity of observing, and from the history of many of those which I have seen recorded, it seems probable that most of the changes observed in the colon have been consequent upon asthenic inflammatory irritation, with diarrhœa, and occasionally with a dysenteric or an irregular action of the bowels, which had existed at some time or other during the course of the mental disorder, and especially at a late period of its progress. Dr. Percival (*Dublin Hospital Rep.* vol. i. p. 144.) observes, "that, on the dissection of cases of insanity which have terminated fatally from chronic diarrhœa, the intestines generally exhibit an extensive mass of disease. The mucous membrane is inflamed, thickened, and partially eroded, and the area of the canal diminished, often considerably, in the lower intestines." The mesenteric glands are often found more or less enlarged and indurated. In addition to these changes, hæmorrhoidal tumours and fistula in ano are not rarely met with in dissections.

246. *B*. Although much importance was formerly attached to disorders of the *liver* in causing insanity, yet the researches of recent writers do not tend to confirm the frequency of this connection. Esquirol, S. Pinel, Guislain, and Foville

found comparatively few cases which presented organic changes in the liver and biliary apparatus. It is probable that lesions of the liver, in connection with insanity, are more frequent in this country than in France, when we consider the influence of the abuse of ardent spirits in causing both insanity and liver diseases. In a case attended by Dr. Sutherland and myself, at the time of writing this, the liver is greatly enlarged. The frequency, indeed, of biliary disorder in the insane cannot be doubted; and the occasional association of organic lesions of the biliary organs with mental disorder will be allowed. The chief doubt, in cases where these organs present alterations, will be as to the nature of the connection; for it will be admitted, that disease of the liver will sometimes affect the functions of the brain sympathetically, and that disease of the brain will exert a similar sympathetic influence upon the functions of the liver; and hence the priority of affection of either of these organs will not readily be ascertained.

247. *C.* Alterations of the *gall-bladder, calculi* in this viscus or in the hepatic ducts, lesions of the *peritoneum* and *omentum,* of the *mesentery* and *mesenteric glands,* of the *pancreas* and *spleen,* of the *kidneys,* and of the *uterus* and *ovaria,* have been severally found in the boidies of the insane, by Bonet, Schulze, Marcard, Oberteuffer, Piderit, Jones, Percival, Powell, Stark, and others; but these have probably been accidental lesions, although they may, in a few instances, have had some influence in causing mental disorder, particularly in persons otherwise disposed to it, by affecting the organic nervous energy in general, and especially that portion actuating the brain.

248. VI. Causes of Insanity. — Few subjects are of greater importance than a just recognition of the numerous causes of insanity,— of their individual and combined modes of operation,— of the influence they exert in various forms of succession, — and of the progressive changes they induce before the effect upon the mind is fully developed. And the importance of the matter is not limited to its bearing upon the treatment of the malady; but is even still greater in respect of prophylactic measures, and of rational plans of mental hygiene. In discussing this subject, I shall consider — *first,* the predisposing causes, or the numerous circumstances which render the mind more susceptible of, or prone to, disorder, than in its natural and healthy state; and, *secondly,* those causes which more immediately produce or excite the disorder. And it must not be overlooked, that whilst the individual influences comprised under the former class are often variously associated in creating a susceptibility or proneness to mental disorder, the occasions or causes belonging to the latter class frequently act also in conjunction, or in immediate succession.

249. i. The Predisposing Causes are the most important objects of study, particularly in respect of their bearing upon hygienic and prophylactic measures. The prevention of so terrible an infliction, as insanity is, must be even of more importance than its cure; since the person who has once been insane, seldom wholly regains his former social position, but is regarded with more or less suspicion, and a union with him is avoided by prudent families. The discussion of this class of causes assumes, moreover, increasing interest and importance, when we consider, that many of the circumstances comprised by it are of more frequent occurrence now than formerly, and are more influential in exhausting, weakening, and dissipating the mental powers in the present state of society, than in former epochs of civilisation; and that several of them may be even viewed as altogether arising out of existing social relations.

250. *A. Constitutional predisposition* is amongst the most predisposing causes of insanity. It may arise — *first,* from a certain conformation, temperament or physical and mental constitution, derived from the parents, — or, *secondly,* from an original predisposition or conformation, independently of disease in any of the parents, — or, *thirdly,* from a state of constitution gradually acquired, or arising out of the continued operation of causes which deteriorate or otherwise change the organic nervous and vital powers, and consecutively the digestive, assimilative, and effective functions. In the *first* of these modes, the predisposition is transmitted from the parents: in the *second* and *third,* it is generated *de novo,* and subsequently admits of transmission to the offspring, although not so certainly as in the first case.

251. *a. Hereditary predisposition.* — M. Esquirol states, — and the circumstance is confirmed by the observation of others, — that persons born before their parents had become insane, are less liable to mental disorder than those born after it has manifested itself; and he further observes, that the morbid tendency, or the actual disease, where it is transmitted hereditarily, is apt to show itself in different individuals of a family at a particular period of life. Instances illustrative of this latter circumstance have been adduced by him, and by Dr. Burrows, MM. Falret, Georget, and others. The hereditary predisposition to insanity, M. Esquirol observes, is not more surprising than the predispositions to gout, phthisis, or other diseases. It may be traced from infancy; and it even explains a number of caprices and irregularities which, at a very early period, ought to put parents on their guard against the approach of insanity, and to guide them in the education of their children. In such cases, the education should tend to render the body robust, and to give tone to the nervous system. The constitution of the offspring should be changed as much as possible, by placing them in circumstances different from those which surround them, or which have influenced the constitutions of the parents.

252. In some instances, one particular form of insanity is transmitted; either dementia, mania, melancholia, or states of mental disorder followed by suicide, being thus observed in the same family. The particular variety of insanity evidently depends upon the temperament, which, with the predisposition to this disease, is derived from the parents. Not only the same form of mental disorder, but also the same physical disease complicating it, or terminating it, are apt to appear in the same family, more generally, or even exclusively; yet there are frequent exceptions to this rule. Where an hereditary disposition exists, different grades of the disorder, rather than different forms of it, are commonly observed, — in one, merely various eccentricities; in another, partial disorder of the moral powers; in a third, disorder of the understanding; and, in a fourth, mania, dementia, &c. In families, also,

in which insanity is hereditary, there is occasionally observed a greater tendency to diseases of the nervous system, than in other families, — as, to epilepsy, chorea, convulsions, palsy, &c. Dr. PRICHARD justly believes that a constitutional tendency existing hereditarily, or arising in the other modes about to be pointed out, is more important, in respect of the frequent occurrence of insanity, than all the other causes taken together. It cannot be said, with propriety, alone to give rise to mental disease, without any exciting occasion; but, if it be very strong, mental disorder will follow the operation of ordinary or very slight causes.

253. Dr. BURROWS remarks, that ESQUIROL assigns only 152, out of 264 cases, in his private practice, to this cause; but that an hereditary predisposition existed in six sevenths of the whole of his own patients. The most exempt from this taint were those whose mental disorder had a sympathetic origin; as in puerperal mania. Out of 57 cases of this latter affection, he could trace an hereditary taint in only about one half. But, where it existed, the disorder was more apt to return. Dr. BURROWS considers that this cause is more common in the higher, than in the lower classes; as the former most frequently marry in their own rank, or even in their own families; and that wherever the system of clanship, or family connection, has been most strictly preserved, there it most prevails. Examples of this are said to have been numerous in the old Highland families of Scotland; and BOËTHIUS mentions some very stringent measures which they adopted, to preserve from hereditary maladies, or rather to prevent the procreation of those who might be tainted by them. That hereditary influence is less common in the lower classes, than in the higher, is shown by Sir W. ELLIS's report of the Middlesex Lunatic Asylum. There, only 214 cases, in which the disease was inherited, were ascertained, out of 1380 patients admitted; and for 125 of these cases, no other cause of the malady than this could be assigned. It has been supposed, that numerous instances of insanity occur among the Jews, from the circumstance of their having kept themselves more free, than all other races, and for a longer time, from intermarriage with strangers. I believe that mental disorders are frequent among them; but other causes may contribute to the frequency. Dr. BURROWS states, that the youngest insane patients he ever had, belonged to a family of this race; and that in it he has observed the father and mother and six of their children insane. He further remarks, that insanity is very prevalent among Quakers, who usually intermarry in their own fraternity.

254. It may be presumed, that, when an hereditary predisposition to insanity exists in both sides of a family, the risk to the offspring will be much greater, than when it is in one side only; and that, when this latter is the case, the child, who bears a very marked resemblance, in constitution and mental character, to the parent exempt from hereditary taint, will be most likely to escape the mental disorder; and the hereditary disposition will fail of being perpetuated by him, unless reinforced by a similar taint, by marriage. But the child that most resembles the tainted parent will be the most liable to experience, and to propagate, the mental malady.

255. There are two points respecting which opinions are often required from physicians,—namely, whether or not a person born of parents who have never themselves been insane, but who, one or the other, is descended from a family thus afflicted, may propagate the malady to his offspring? — and whether or not a child born before insanity had appeared in either parent, is as liable to become insane, as one born after the malady was developed? The *first* question, Dr. BURROWS believes, should be answered in the affirmative, because he has met with insane persons, neither of whose immediate parents had themselves been insane, but some of the progenitors, or an uncle or aunt, on one side or other, had been so afflicted. I have known cases, where the nearest progenitors to the patients, who had been disordered in mind, were grand-aunts or grand-uncles. The *second* question has been partly answered above, (§251.), by M. ESQUIROL. But Dr. BURROWS considers, that a child born, either before or after the accession of insanity in the parent, provided that parent's progenitors or relations of blood had been insane, is liable to the malady; but that, if the insanity of the parent were adventitious, and not hereditary, the child born before mental disorder had appeared, will not have it by inheritance: how far a child born after the occurrence of adventitious insanity, is liable to mental disorder, is decided with difficulty. This writer believes that, whether it be adventitious or hereditary, once occurring, the morbid diathesis is thereby stamped, or generated.

256. *b.* The offspring may possess a *connate predisposition* to insanity, although neither of the parents, nor of the grand-parents, nor any member of their families, had been the subject of it. BURTON long since remarked, upon the authority of the older medical writers, that the offspring procreated of parents when they were far advanced in age, are more subject, than others, to melancholy madness. There can be no doubt, that whatever produces enervation or debility in the parents, will occasion a certain amount of predisposition in their children to nervous affections and to mental disorder; and I believe that habitual drunkenness, or the abuse of spirituous liquors, by either parent, and especially by the mother during gestation and lactation, causes numerous diseases in the offspring, and more particularly disorders of the functions of the brain, and nervous system in general. It also is very probable, that the children of persons who have been weakened by premature or unnatural sexual indulgences and vices, or who are gouty, hypochondriacal, hysterical, or otherwise debilitated, will be more susceptible of the operation of the exciting causes, than the offspring of those who are constitutionally robust and healthy. M. ESQUIROL affirms, that many facts have been observed by him, proving, that a strong predisposition to madness has arisen from fright or terror sustained by the mother during pregnancy; and that marked cases of this kind occurred during the French revolutions.

257. It has been long and generally supposed that marriages within a confined circle, as between cousin-germans, have the effect of impairing both the mental and constitutional powers of the offspring. The opinion seems well founded, and is undoubtedly just, if the breeding in-and-in be continued for two or more generations. The children of such families often die in infancy or

early youth; are frequently scrofulous, and are liable to hydrocephalic and convulsive diseases; and, if they grow up, are frail in body and imbecile in mind, or predisposed to mental disorder. — It is doubtful how far the scrofulous diathesis may dispose to insanity; but I believe that it has a very considerable influence.

258. *c.* That there may be not only — 1st, *an hereditary*, and, 2dly, *a connate*, but, also, 3dly, *an acquired, predisposition of constitution* to insanity, I firmly believe. This last state is quite independent of the two former, and of temperament or diathesis, and is generally the result of the operation of debilitating causes during infancy, childhood, and the periods of puberty and early adult age. Indeed, many of the moral and physical exciting causes may have this effect, when acting in a slight but continued or constant manner. But there can be no doubt, that early indulgences; a tender, sensual, and luxurious education; vicious modes of early instruction; masturbation, and premature or vicious sexual indulgences; exhausting pleasures, and inordinate mental and physical excitements, relatively to the states of nervous and constitutional energy; and various other causes, which debilitate the frame, increase the general sensibility, and augment the susceptibility of the brain and nervous system, — will often develop, to a greater or less extent, a predisposition to insanity, which may be appropriately termed acquired.

259. It has generally been supposed, and poets have sung, that a great genius is closely allied to insanity. This is most erroneous. Persons with a too active and ill-regulated imagination are predisposed to mental disorder; but those who possess powerful intellects, and a vast range of powers and of intelligence, are much less disposed to it than others; and, if they have become insane, the causes have been of an energetic kind, and overwhelming from their activity or association.

260. *B. Temperaments, &c.* — Persons of the melancholic temperament are more liable to the melancholic states of insanity, than others; those of the nervous temperament, to mania, dementia, and monomania; and those of the sanguine, or sanguineo-nervous, or irritable temperaments, are attacked more frequently with mania, than with any other form of mental disorder. M. Esquirol observes, that, when persons of the lymphatic or phlegmatic temperaments, or of a pale exsanguineous habit of body, are affected with mania or monomania, dementia or incoherency is more liable to supervene in them, than in others. This form of insanity is also likely to follow in persons of a full habit of body, with a thick head and short neck. — Mental disease pursues a somewhat different course in persons of different temperaments. Choleric or warm constitutions, or those with black hair and eyes, and vigorous frames, become violently maniacal, but experience a shorter disorder, and more frequently terminating in a marked crisis, than others. Individuals of a fair, pale complexion, with light hair, fall more readily into chronic mental disease: the dark-haired are liable to become gloomy monomaniacs; red-haired lunatics are disposed to violence, and are treacherous and dangerous. He gives the following table of the general appearances of a number of lunatics: —

External habit of body	Of the medium fulness of habit	122
	Thin or emaciated	60
	Fat	6
Height	Tall	102
	Short	19
The eyes	Chestnut or brown	102
	Blue and light	98
	Black	17
The hair	Chestnut	118
	Fair or flaxen	39
	Grey or white (aged)	36
	Black	31

261. *C.* The *form of the head in lunatics* has attracted the attention of Greding, Pinel, Georget, Gall, Spurzheim, and others. M. Pinel believed that there are certain peculiarities in the shape of the skull, frequently observed in the insane, and particularly in cases of dementia and idiotcy. The two most prevalent forms which he specifies, are — 1st, a laterally compressed shape of the head, giving a very long diameter from the occiput to the forehead; 2dly, a short and almost spheroidal form, — the above diameter being shorter than usual. He could not, however, detect any mental conditions corresponding with these opposite shapes. M. Georget states the results of the examination of upwards of 500 heads in the collection of M. Esquirol. One half of these presented nothing remarkable, being regular and well formed. The other half were more or less peculiar in the form and appearance of the skull, and in the thickness, density, and organisation of the bones composing it. Some skulls were unequally developed, — one side being more arched and larger than the other, especially the right. Others were somewhat oblique, — one side of the head being too forward, and the other much behind. I have seen instances where these two malformations were conjoined. M. Georget found some skulls in this large collection, in which the antero-posterior diameter was not more extended than the lateral: in these, the cavity was much elevated, especially in the posterior part. The cavities of the base of the skull presented likewise inequalities: those of one side were sometimes larger than those of the other. Persons who have contracted heads, particularly as now described, not only are more liable to insanity, than those whose heads are well formed, but lapse more readily into a state of dementia or fatuity, and are consequently less curable than others. It is chiefly in these hopeless forms of general insanity that these irregularities of the form of the head are observed. In *idiots*, as I shall show hereafter, these malformations are still more remarkable.

262. *D. Sex.* — The ancients, and especially Cælius Aurelianus, supposed that insanity occurred more frequently in males than in females. Recent investigations, however, have shown this not to be generally the case, in modern times. Dr. Prichard quotes M. Esquirol, as stating the proportion of insane females in France, to insane males, to be 14 to 11. M. Voisin considers the proportion as 13 to 10. In all Italy, the proportion is different — it being about 5·65 males to 5·00 females. M. Guislain states, that in Holland and Belgium, the number of lunatic females, to males, is as 34 to 29. Dr. Prichard assigns the proportion in Great Britain and Ireland, of male to female lunatics, as 13 to 12; and observes that, in England, the number of insane men, compared with that of women, is more considerable than in Scotland and Ireland; and this excess on the side of the males is greater, according to Dr. Burrows, in the higher than in the lower classes of society.

M. ESQUIROL confirms this observation in respect of France; and further states that, in the North of Europe, — in Germany, Denmark, Norway, and Russia, — the proportion of male to female lunatics is as 3 to 2. Dr. JACOBI furnishes nearly the same results in regard of Prussia. In the United States of North America, the number of insane males is stated to be much greater than that of female lunatics. In the States of New York, Pennsylvania, and Connecticut, the proportion of the former to the latter is nearly 2 to 1. In summing up the results of his inquiries obtained from various parts of the civilised world, M. ESQUIROL finds that the general proportion of insane males to females is about 37 to 38.

263. The occurrence of insanity among females is partly owing to the nature and vices of their education; to their greater sensibility and keener feelings; to the restraints imposed upon their desires and emotions; to the crosses, chagrins, and disappointments to which they are liable; to reading romances and novels, and thereby exciting the imagination, without improving the reasoning powers; to the addiction to music, and the want of salutary and invigorating occupations; and to the life of celibacy they are often doomed to lead. These, and various other moral causes, about to be noticed, contribute remarkably to the production of insanity among females.

264. The physical causes also operate energetically in producing insanity among this sex; but they are chiefly disorders of the sexual organs. Irritation of the uterus, or of the nerves supplying it, and its appendages; suppression, retention, or inordinate flow of the menses; and various organic lesions of these parts; have a very marked influence, sympathetically, upon the functions of the brain. Many of the moral causes, and emotions of mind, have but little influence, until they have first disordered the functions of the womb; and as soon as this organ is disordered, it reacts upon the brain, and heightens the effects of the moral emotions. In such cases, as well as in many others common to both sexes, the moral causes are often insufficient to induce the mental disorder, until they have first occasioned physical disturbance in some organ; which disturbance, from its sympathetic influence upon the brain, becomes an additional cause of the disorder. Females, however, are often so circumstanced as to experience very serious disorder of the circulation of the brain, from energetic mental emotions, occasioning an immediate effect upon the manifestations of this organ, before any disorder can appear elsewhere. And, in some cases, the consequent disorder is produced almost simultaneously in both the brain and the functions or state of the uterus. We observe this especially in the puerperal states, and, still more particularly, soon after delivery.

265. M. ESQUIROL remarks, that females become insane at an earlier period of life, are more liable to lapse into dementia, and are more disposed to religious insanity and to erotic delirium, than males; and that all varieties of insanity, in them, are generally complicated with hysteria. Males, on the other hand, are more liable to mania and violence; they are more dangerous, and more difficult to restrain: women are more noisy; cry, and talk more; are more dissembling, and less readily confide in those about them.

266. *E. Age.* — Insanity, in the forms which have been described, is rarely observed before the age of puberty. Imbecility and idiotism are always observed in childhood; but the instances, in which any form of true insanity has occurred at any epoch before puberty, are very few. They have, however, been recorded by J. FRANK, Dr. HASLAM, M. FODÉRÉ, M. ESQUIROL, Dr. PRICHARD, and one case occurred in my own practice, and that was caused by fright. Two cases mentioned by M. ESQUIROL proceeded from the same cause. He met with one case of melancholia complicated with marasmus, in a child eleven years of age, remarkable for his large head and mental precocity. Instances, however, more frequently occur of children becoming melancholic, and even delirious, from jealousy and envy, than is generally supposed. They sometimes are thus affected, although often only temporarily, by seeing the attentions of those to whom they are much attached, bestowed upon others; and by being outstripped in obtaining distinctions at school.

267. After fifteen years of age, insanity ceases to be a rare occurrence. About the period of puberty, in females, or when the catamenia are about to be established, melancholia and mania occasionally appear, and especially if the growth be rapid, and the catamenia are retained, suppressed, insufficient, difficult, painful, or irregular. In these cases, and still more so at a later period, hysteria is generally attendant upon the mental disorder. During the first few years after puberty, in the male, mania and melancholia not infrequently occur; the former generally from the excitement of sexual desires, the latter from masturbation or venereal excesses. M. ESQUIROL remarks, that mania, in all its forms of excitement, appears chiefly in early life; melancholia, in middle age; and dementia, in the advanced epochs of existence. In youth, insanity assumes an acute and violent course, and often terminates by a remarkable crisis: in middle age, it is more prone to become chronic, and is oftener complicated with disorder of the abdominal viscera; but is sometimes resolved by hæmorrhage from the hæmorrhoidal vessels, or by diarrhœa. At an advanced age, it is apt to pass into dementia, and to be complicated with paralysis, apoplexy, &c.; and recovery is much less to be expected. However, dementia may occur in the young; and very aged persons may be attacked by mania, and recover from it, — but these are only exceptions from the rule just stated.

268. The *ages* at which insanity most frequently appears, are — that between 30 and 40; next, that from 20 to 30, and from 40 to 60. M. ESQUIROL, however, states, that the maximum number of admissions of cases of insanity take place from 30 to 35 years of age: that each five years, from 20 to 35, give nearly the same number: that the admissions of males are more numerous from 25 to 30; and those of females, from 35 to 40: that the periods from 30 to 35 follow thereafter, for the men; and from 40 to 45, for the women: and that the admission of males from 20 to 25 years of age occupy the third rank of frequency; whilst those of females hold only the sixth rank. From this it follows, that insanity is most frequent at an earlier age in men, than in women. M. ESQUIROL further states, that the wealthy classes are much earlier attacked — or

rather, are affected in greater numbers at an early age — than the laborious. M. GEORGET adduces the following calculation of the ages of insane persons, on admission into several institutions in England and France: —

From 10 to 20 years of age	365
20 to 30	1106
30 to 40	1416
40 to 50	861
50 to 60	461
60 to 70	174
70 and upwards	35
	4409

269. Yet, although a greater number become insane from 30 to 40, than at any other age, still the number may not be really greater, relatively to the proportion of persons in society of farther advanced ages; and hence, 174 instances of the malady occurring in persons aged between 60 and 70, may actually show a greater prevalence of it at that age, than 1416 cases appearing between 30 and 40 years of age. That this, however, is not the case, — and that a greater number, relatively to the proportion of persons existing in the community at that age, actually become insane between 30 and 40 years, — is proved by the number of persons surviving out of each 1000 at successive periods of life. In this country, 410, out of each 1000 born, will reach 30; and 345 will reach 39; but 220 will reach 60, and 140 will attain 70; and if the mean number of those between 30 and 40 thus be 376, and that of those between 60 and 70 be 146, it will be at once manifest, that the number of instances of the invasion of insanity is, relatively to the proportion of persons between 30 and 40 years of age, actually greater at that period.

270. M. ESQUIROL, however, believes that a proportionably increased frequency of mental disorder, with the advance of age, really does obtain, although the predisposition, thus arising from advancing age, increases in an irregular manner. The increased number of insane persons, he adds, compared with the population of that age, is very striking between 50 and 55 years. From 70 to 75, and from this age to 80, it becomes enormous, owing to the frequency of senile dementia. This is very probably correct; but it must not be overlooked, that a very large proportion of the cases of hereditary insanity occurs between 30 and 40, or even earlier; and it is admitted, that these cases constitute the great majority.

271. *F. Education.*—There are few causes which more powerfully predispose to insanity than erroneous education and moral discipline in early age. —*a.* Too great indulgence in childhood, and previously to, as well as during, puberty, and a want of moral discipline then and up to manhood, with neglect of that education, which inculcates, and, indeed, enforces, proper principles of feeling and action, are undoubtedly amongst the most deeply laid foundations of insanity. Persons thus brought up, have their temper, emotions, and moral affections so little under command, — are so subject to ebullitions of passion, to caprices, or violent and fugitive emotions, — are so liable to act from momentary feeling and impulse, — as to acquire a disposition of mind, or moral character, not only most unamiable in itself, but also most prone to marked disorder, when subjected to its more immediately productive causes.

272. *b.* The premature and overstrained exertion of the mental powers is another most important cause of predisposition. In the higher and middle classes of society, the mind is excited much beyond its powers; and the child, being required to perform too much, with its imperfectly developed faculties, experiences, as a consequence of such premature excitement, increased vascular action in the brain and its membranes, at a period of life most disposed to vascular disorder in this organ; and the foundation is thus laid for chronic disorder, and especially for chronic inflammatory action of that part of the nervous system with which the manifestations of mind are most intimately allied. The quantity, as well as the diversity and range, of mental exertion, now required from both sexes at a too early epoch of childhood, and during the period which elapses from mere infancy to puberty, while both mind and body are only in an early stage of formation, must necessarily prove injurious, both mentally and physically, — and especially to those who are either delicately constituted, or tainted by any hereditary disposition to insanity. Therefore, when this disposition exists, not only should premature and overstrained mental exertion be avoided, but also should the feelings, the passions, and the actions be subjected to strict discipline — to a discipline not too harsh or rigid, but rational and consistent. The mind ought to be formed under a kind restraint, and imbued with correct principles, and with a due sense of moral and religious responsibility. In the present day, too much attention is paid to an early cultivation of intellect, and to the mere acquisition of knowledge of facts and phenomena, to the neglect of the education of the moral affections, and of just principles of feeling and of acting. The great ends of education, as now conducted, are, as respects the one sex, the attainment of that knowledge and of that range of information which may enable its possessor most successfully to compete in the general scramble for wealth, for advancement in society, or even for existence; and, as regards the softer sex, the possession of such accomplishments, and the acquisition of so wide and so superficial a range of ideas, in a very limited period of time, as may strike or captivate, or may be more readily and generally made available in society, and thus become the current coin of the mind in conversation. These objects are pursued in education in a manner but too well calculated to overstrain the early intellect, to exhaust the feeble mind, and to derange the hereditarily predisposed. The mind is engorged with food, not of the most wholesome or digestible quality, beyond its powers of healthy digestion and due assimilation, and even before these powers are fully evolved; and hence, but too frequently, follow disorders, varied in extent and intensity, of its most important and effective manifestations or functions.

273. *G. Climate and Seasons.* — *a.* It is very doubtful what degree of predisposition can be ascribed to climate and seasons, especially as most of the differences in the numbers of the insane in different *climates*, may be attributed to various moral and physical circumstances not necessarily dependent upon climate. In warm climates, and even in Turkey, and other Mahommedan coun-

tries beyond the tropics, and in hot climates, where the minds of the population are under the sway of the Romish and Greek churches, insanity is much less frequent, than in temperate and highly civilised countries. M. ESQUIROL, in accounting for the greater prevalence of insanity in temperate climates, attributes too much importance to sudden alterations or vicissitudes of temperature. The greater frequency of the malady in these climates is plainly attributable to other causes than this. I believe, however, that a predisposition to insanity, and particularly to connate and puerile imbecility, and to dementia, is to some extent generated by marshy or miasmatous places, particularly in low districts subject to inundations, and in low valleys placed deep between precipitous mountains. There, the mind and body are checked or weakened in the course of development, and the latter early becomes the subject of diseases which impair its vigour and further weaken the powers of mind.

274. *b.* The *seasons*, according to M. ESQUIROL, have some influence in causing insanity,—but probably more as exciting, than as predisposing, causes. High ranges of temperature seem to have considerable influence in causing or in determining the character or form of the disorder, and particularly mania, or the higher states of the malady. M. ESQUIROL has given a table of the admissions into the *Salpêtrière*, during each month, for nine years, according to which it would appear, that the lowest number was admitted in January; and that the admissions increased progressively from March till July, when they reached the maximum. They then progressively decreased till October. From this month to March they varied somewhat in number, but not so much as to excite speculation.

275. *H. Professions, Employments, &c.*—*a.* The frequency or infrequency of insanity amongst persons pursuing certain professions or employments, is obviously to be referred to the several circumstances more immediately connected with these employments; but most of these circumstances will be more fully considered hereafter. The learned professions certainly furnish fewer cases of insanity, relatively to the numbers exercising them, than any other class of persons in the middle ranks of the community. This, probably, is owing to the education for the professions, in early life, being such as tends more than any other to develop, and to strengthen, the judging and reasoning powers, without exciting the imagination, or prematurely involving the feelings and passions. Some exceptions, however, may be found among young divines, who, from enthusiasm or anxiety respecting the state of their minds, have become partially or altogether insane; but such cases are comparatively rare amongst the soberly and regularly educated.

276. *b.* I believe that insanity is most prevalent among artists, musicians, and actors, relatively to the number of persons pursuing these occupations. This frequency obviously depends upon a great variety of circumstances, many of which will be found amongst the moral causes of this malady. In the present day, — for it was not so formerly, and in the palmy days of Italian art, — few artists receive an education, in early life, calculated to develop, or to strengthen, the intellectual and reasoning powers. The imagination is early and almost exclusively exercised; and many of the instinctive moral affections of mind (see note, § 66.), which exert so powerful an influence upon mental sanity, are so often brought into inordinate action, without the due control of sound judgment and strict principle, that first partial, and ultimately general, insanity is the more liable to appear. Besides, artists, in the wide acceptation of the word, are liable, in the exercise of their art, to sustained excitement, not merely of the imagination, but also of the feelings and passions, — to a certain tension of the mind, — tending to exhaust, and at length to disorder, the intellectual powers. There are few classes, moreover, who entertain more extravagant ideas of their own merits, than those to whom I now refer; and who, consequently, are more liable to jealousy, envy, disappointments, and wounded self-love. Poets and literary men are liable to the same imputations, — entertain the same ideas of themselves, and of others, as those who may be classed under the general denomination of artists; but, in general, their education is sounder, and better calculated to strengthen the reasoning or controlling powers of mind. In all, the sedentary occupations, the insufficient exercise in the open air, and the irregularities of living, or the alternations of abstinence and dissipation, aid the moral causes of the malady, in this class of the community.

277. *c.* It must necessarily follow, that insanity will vary in frequency, in different professions and employments, with the degree in which they respectively call into exercise those moral emotions or causes on the one hand, and the physical circumstances on the other, on which this malady has been found more especially to depend. Next to artists, in the liability to mental disorder, may be ranked, according to the tables of M. ESQUIROL, merchants and traders, and military men. This may be expected, especially if brokers or speculators in the funds or share markets are included under this head: and, indeed, merchants, traders, manufacturers, and speculators or gamblers in all kinds of securities or pseudo-securities, have, in recent times, so entirely fallen within the same category; and are, from the governor or director of the most powerful corporate bodies in the world, down to the very humblest adventurer in a bubble company, so generally and completely subjected, from the nature of their engagements, — from the epidemic scramble after gain at all hazards,— to alternate excitement and depression — to elated expectations and painful anxieties — to hopes and fears — to fortunate anticipations and humiliating disappointments; and have the prospects of being, or are, in fact, one day as rich as Crœsus, and the next even poorer than the meanest slave, — that the mind, which probably has never been strong, nor duly strengthened by wholesome education, and by the early inculcation of sound principles of feeling and acting, at last experiences, and manifests, the shock, in some one of the various forms of insanity. Shall the medical philosopher — contemplating the present state of society, seeing these things, and knowing the circumstantiality with which insane acts and crimes are published, commented upon, and rendered interesting to vulgar tastes and minds — be surprised at the existing prevalence of insanity, and one of its most common results — suicide? The weak, the injudiciously tutored, and the pampered, mind, after a career of ill-deserved prosperity, — a prosperity often as iniquitously enjoyed

as unjustly earned, — not infrequently experiences a reverse, which it is incapable of enduring without more or less of mental disorder; but the reverse is commonly attended by circumstances involving also many confiding and innocent persons; and thus more than one sustains a shock, before which reason is shaken or entirely overthrown.

278. I. *Previous attacks of insanity, or other diseases of the brain*, greatly increase the susceptibility of mental disorder. Although recovery from insanity often takes place without any subsequent manifestation of mental disease, and although even repeated attacks have been sustained, and a complete and permanent restoration has occurred nevertheless, — yet much more frequently madness leaves the person, who has once been its subject, much more prone to a return of it. In many cases, the patient continues, for a long period after recovery has apparently been established, more irritable and excitable than previously to the attack: he is irascible; very susceptible of impressions; and less capable of application to business, or of mental exertion. After every successive attack, this change in temper and character becomes more manifest, until the disease assumes a remittent, and ultimately a continued, form; a state of permanent incoherency or imbecility ultimately supervening.

279. Inflammations of the brain or of its membranes, frequent attacks of epilepsy, apoplectic and paralytic seizures, and fevers with predominant affection of the brain, often predispose to mental disorder. Indeed, these maladies are not infrequently both attended and followed by delirium, or some form or other of insanity, which generally disappears in a few days, or at most weeks, after the primary malady has evinced signs of amendment, or after recovery from it has taken place. When either of these cerebral diseases are thus complicated, the danger of the recurrence of a temporary, or a severe, or even a permanent, attack of insanity, or of a return of the primary disease, attended by a more complete overthrow of the mental powers, is much heightened. This is especially the case in respect of epilepsy, particularly when slight partial paralysis with mental disorder follows the fit. In such cases, incoherency, imbecility, and, ultimately, fatuity, often successively appear. In some instances, where the epileptic paroxysm is attended by violent mania, which subsides in a few days afterwards, the mental derangement gradually becomes permanent, and either supersedes the epilepsy, or continues complicated with it. When insanity is thus caused by epilepsy, sullenness, sudden irascibility, with a disposition to commit the most atrocious acts, and various manifestations of moral disorder, often characterise the malady.

280. ii. THE EXCITING OR PRODUCTIVE CAUSES. — Certain of the causes which have been already considered, may, from their nature or intensity, give rise to insanity, without the aid of any exciting occasion, or, at least, of any so marked as to attract the notice of the patient's friends. On the other hand, many of the causes about to be noticed, either from their slight but often combined action, or from their continued influence, actually predispose to, rather than excite, insanity; or they affect so slowly and imperceptibly the mental powers, as well as the bodily functions, without giving rise to any sudden or manifest shock of the mind, as to change the character or constitution of both, and thereby fit or prepare them for the injurious impression of causes which would otherwise have been entirely innocuous. — The exciting causes have been very commonly divided into *moral* and *physical;* and under these heads have been also comprised, by some of the best writers, the causes already considered, as creating a predisposition to mental disorder. And when the circumstances just alluded to, respecting the operation of these causes, are considered, there can be but little fault found with this arrangement. Some authors have differed as to the comparative influence of *moral* and *physical* causes in occasioning this malady. But the difference has arisen chiefly from the more extended signification assigned to the latter term by some, and from their having comprised under it various important causes kept entirely apart by others, — and especially the greatest of all causes — hereditary predisposition. Leaving this, therefore, out of the arrangement, or, rather, considering it separately, there can be no doubt of the influence of the moral causes, in the production of insanity, being much greater than that of the physical. Still the matter is not so satisfactorily solved, especially by referring to statistical tables, as may be imagined. For, although it may have appeared, from the information received, that the malady was produced by some moral cause; yet there may have existed at the time, or closely upon it, some physical disorder, and especially some functional disturbance of the digestive, assimilative, and excreting organs, or a morbid susceptibility of the nervous system, or both, without the existence of which the moral affection may have been quite inoperative. Agreeing, however, with HEINROTH, PINEL, GEORGET, GUISLAIN, PRICHARD, and others, as to the great and predominant influence of moral over physical causes in the production of insanity; still, even in the cases where they seem to have been most influential, various physical or functional states or disorders may have existed, so as to predispose the nervous system to be affected by them; or the moral emotion may have first occasioned some severe physical diseases, of which the mental disorder was the more immediate effect.

281. In proof of the predominance of moral over physical causes, most writers refer to the great frequency of insanity among highly civilised people, and its almost entire absence from savage or barbarous nations. The data, however, are not to be depended upon, as respects savage communities. It is not correct to say, as many have, that insanity is unknown among them. It certainly is comparatively rare, or very seldom occurs, — but it does occur amongst the greatest of all savages; various circumstances, however, preventing persons in this state from being long troublesome to their friends or to the community, — or, in other words, once an individual "loses his head," — as the being insane is very generally termed, — he is soon got rid of; and his insane acts, before his state is recognised, often directly or indirectly terminate his existence. On this subject Dr. PRICHARD remarks, that, "in a barbarous state of society, the passions are under no restraint — the emotions are impetuous; hatred and malignity are in perpetual exercise; the fierce and sensual desires which are common to mankind and the inferior tribes, are indulged without limit. Nor

are the intellectual faculties without their exercise in carrying on the stratagems of barbarous warfare. We should conjecture that such a state of society, in which the passions are in perpetual and violent agitation, would not infrequently produce insanity." Still, I contend that these are not the chief moral causes of which this malady is so frequently a result; and that many of the physical disorders, which either predispose to, or produce, mental disorder, and which remarkably aid the operation of moral causes, are not very common in savage communities. If we contrast the emotions which powerfully affect the human mind in civilised society, with those which have been just noticed, the consequences resulting from the former to the mind itself, may be, in some measure, anticipated. When we consider the premature and excessive exertion of the faculties in highly civilised countries; the restraints imposed by social institutions and legislation, and the consequences which often arise out of them; the diversity of interests and of feelings brought into action by many pursuits, upon which wealth, honour, and even existence, depend; the long-continued anxieties, griefs, disappointed hopes, the family dissensions, and injured or lost affections; the chords of feeling too intensely strung; the prolonged or intense mental exertion; the continued tension of the imagination, or of the intellectual powers; the pride, ambition, and humiliations; the distractions of the mind by religion, by worldly speculations, and diversified engagements; the sudden reverses, the jealousies, and the numerous causes continually impressing the moral sentiments and affections, and increasing the susceptibility of the nervous system, as well as disordering the general health, — when we contemplate the prevalence, the frequent recurrences, and often the almost constant operation, of all these circumstances in civilised life, we cannot be surprised at the effects produced by them upon the mind and nervous system; especially when we find that they seldom act singly, but generally in combinations, or associated with various predisposing and exciting or determining causes.

282. There are, also, other considerations, not to be overlooked in attempting to account for the greater prevalence of insanity in civilised than in savage communities. Children of weak physical powers are seldom reared among the latter; and the higher intellectual faculties, and the finer and more elevated moral affections, — especially the powers of intellection, and the rational emotions of mind (see note, § 66.), — are imperfectly developed in them, and consequently less prone to experience or to originate mental disorder. In barbarous societies, the mind retains much of the constitution and character presented by it in childhood and boyhood in more civilised communities: it is incapable of comprehensive views and combinations of thought, or of prolonged exertion; it retains the sanguine disposition of youth, and is little susceptible of care and anxiety, and thinks of little, but of present gratification and ease. On the other hand, whilst civilisation develops all the finer emotions and affections, all the higher and more reflective faculties, and augments the susceptibility of the moral feelings, as well as the general sensibility, it tends also to disorder them the more, owing to numerous resulting circumstances, which inordinately excite or seriously disturb them, and which thereby often ultimately overthrow them altogether.

283. M. Georget, however, most probably over-rates the influence of moral causes in the production of insanity. He believes that 95 out of 100 lunatics have become so from the operation of the affections and moral emotions; and he states this to have been the opinion also of M. Pinel. It is in the age, he adds, in which the mind is most susceptible of strong feelings, and in which the passions are excited by the strongest interests, that madness is principally displayed. It is chiefly, however, in the higher and middle classes of society that the moral causes are most productive of insanity. This is shown by the researches of Esquirol, Georget, Guislain, and others. It is in them that the influence of civilisation, in increasing the frequency of the malady, is especially manifested; thus proving the justness of the remarks which I have ventured above, and which are partly founded upon my observation of the state of society in savage communities. Amongst the lower orders, physical causes have more influence than in the higher; and, of the moral causes, an unrestrained sway of the temper and passions is the most manifest. Physical causes are, according to the writers just mentioned, more influential in females than males; and, in the former, amongst the lowest classes, I would add, that violence of temper is the most productive moral cause of the malady. — In further considering the *exciting causes*, I shall offer a few observations — 1st, on the more remarkable emotions of the mind, of which insanity is often a consequence; 2dly, on the physical causes of the malady; and, 3dly, on certain circumstances in the general habits and manners, and in the social and political states, of our species, resulting from various combinations of moral and physical causes, which both indirectly and immediately occasion mental disease.

284. *A.* Of certain Moral Emotions. — *a. The more violent passions and emotions*, sometimes, by their sudden or vehement action, more or less disorder the functions of the brain, — especially violent anger, and terror. Unrestrained bursts of temper are very frequent causes in the lowest classes of the community, and particularly in females — in whom it acts either directly on the brain, or consecutively, by first disordering the uterine functions, or in both modes. M. Esquirol, however, assigns a greater influence to fright than to anger; but mania is the form of the disorder which most frequently results from both these causes. Dementia much more rarely is occasioned by them. These emotions are the most intense and the most sudden, of which the human mind is susceptible; and, fortunately, they are amongst the shortest in their duration. The nervous system, and particularly the functions of the brain, are more violently agitated by them than by any other; and in many instances, where no predisposition to insanity exists, fits of convulsion, tremors, and various nervous affections, are caused by them, — especially in weak, nervous, and susceptible constitutions.

285. *b. Care, anxiety, grief, distress, and all the depressing emotions*, are the chief causes of mental disease. In the same category may be included, domestic griefs, and disagreements, family dissensions, ill-assorted marriages, reverses of fortune, disappointments, prolonged fears, men-

tal humiliations, jealousy, wounded self-love. The tables which I shall give hereafter, will show the relative influence of these and other causes in one civilised country. It will readily be admitted, that it is chiefly in communities far advanced in civilisation, that these causes are most productive of this malady. These causes act very generally in combination, either with one another, or with various predisposing and physical circumstances: many of them operate upon the mind slowly and silently, and only by first disordering one or more of the bodily functions. Joy, and the more exciting emotions, less frequently occasion insanity than is commonly supposed. Esquirol states, that the opinion of Mead, as to the frequency of mental disorder from this cause, is not well founded; but he admits the importance attached by Pinel to the struggle between religious and moral principles, and the passions and worldly interests, — a struggle sometimes long sustained, and terminating in impairment of reason, and especially in melancholia. It is not only in their individual, but also in their combined, operation, that the causes of insanity should be studied: and in order that sound principles subservient to rational hygienic and prophylactic measures may be deduced from the study, the various combinations and successions of action should be recognised; and the intermediate changes, mental and physical, ought to be traced as far as the means of investigation may be furnished us. It is chiefly, also, by ascertaining the changes first induced in the functions of important organs, and the succession of morbid actions resulting therefrom, that we can be enabled to form rational or successful indications of cure.

286. *c. Religious impressions, and apprehensions of a future state*, are amongst the most important mental causes of insanity. — *Religious madness*, as it has been termed, has long been an interesting subject to the philosophic physician; and its frequency in Great Britain demands from him a particular notice of the various circumstances connected with it. — I cannot agree with Dr. Prichard, in considering that the number of persons, who become insane from religious hopes and fears, is much less considerable than it is generally supposed to be. The frequency of disorder from this cause varies remarkably in different places and in different times; and the mischief often becomes either endemic or epidemic, from every fanatic, or ambitious preacher, who is desirous of acquiring notoriety, or of being the originator, or the leader, of a particular sect, — from any one, however slightly imbued with religious knowledge, or however ignorant, who wishes to be distinguished amongst those who are equally ignorant, but more honest, with himself, — and from any one, who, already partially insane, believes himself inspired, and called by the Almighty to instruct and convert men, before he is himself even partially instructed, — being permitted to "deal damnation round the land," and to excite the feelings and the fears, or to distinguish the hopes, of the ignorant, the nervous, the susceptible, and of the hysterical, without any control as to education, doctrines, or religious principles. As the numbers of these adventurers increase or diminish, so do the victims of this encouragement to disturb the minds of the community also vary in number. In this vicious plenitude of liberty, every body enjoys not only entire freedom of thinking and speaking, but also of acting. The rogue who is too lazy to work, is allowed, without inquiry into his knowledge, or belief, and without hindrance on account of character or of the mischievous nature of his doctrines, to harass the feelings, to excite the imagination, and to blight the happiness, of many of those who listen to him. It is not seen, or, if seen, in no way guarded against, that the more dangerous the doctrine, the greater the fanaticism, or the more vehement and impassioned the declamation with which it is promulgated, the more intensely are the uneducated affected, and the mind disordered by it. The more absurd and inflated the harangue, the more frantic the manner, and the greater the outrage on common sense and decency, the moral infection sinks the more deeply, and spreads the more widely, until mental disorder assumes a truly epidemic form. That this is not over-stated, is sufficiently proved by what has taken place recently in this metropolis, by the camp-meetings in America, and by the "revivals" in Scotland and in that country.

287. The frequency of mental disorder from this cause has been insisted upon by Darwin, Perfect, Falret, Jacobi, and others, but somewhat doubted by Dr. Prichard. According to my own observation, I believe this to be a frequent cause of insanity in this country, particularly amongst protestant dissenters, — but of very irregular frequency, owing to the circumstances just alluded to. The forms of disorder caused by it are chiefly theomania, melancholia, suicidal insanity, mania, and mania complicated with hysteria. It must not, however, be supposed that religious feelings are generally the only and sole cause of mental disorder, amongst persons whose minds are much engaged with these sentiments; or that all the cases of insanity, in which the mind is occupied with religious ideas, have proceeded either solely or chiefly from this source. In the great majority, perhaps, of instances, other moral causes, or even bodily disorders, have either predisposed the mind to be influenced by these feelings, or have been associated with them in their operation on the mind. Dr. Jacobi observes, that the original cause of derangement is often some misfortune, or some physical influence, — religious ideas rather determining the morbid effect upon the mind, than actually originating it. There is much truth in this, and it is most important in respect of treatment. I have witnessed several cases illustrative of the justness of this view; and, by acting upon it, they have had a favourable issue.

288. The more civilised the human mind, the more desirous it becomes to form anticipations of the future, or to entertain hopes and fears of good and evil, which are not limited to the present state of existence. In forming these anticipations, the knowledge of our own imperfections, and of our numerous acts of demerit, naturally impart to them a certain degree of gloom or despondency; and accordingly we find, in all civilised ages and countries, that these feelings, when inordinately indulged, — especially during states of physical disorder, or when the mind is already depressed by grief, anxiety, and bereavements, — have caused mental disease. Dr. Heinroth has collected numerous instances from the early fables of Greece,

showing, that madness from this cause was not of rare occurrence in the ages of remote antiquity. The circumstances in the moral nature of mankind, on which religious insanity depends, cannot very materially change, and may therefore be expected always to produce their usual effects; still they may be more remarkably predominant, or very much less so, in certain periods and places, than in others; and that they have been, and still are, thus variable, is well known. Dr. PRICHARD observes, that, in France since the revolution, the influence of religion on the community has been less than it ever was in any civilised country; and French physicians have informed him, that cases of religious insanity have become proportionately rare. M. ESQUIROL states, that the changes during the last fifty years, "in the moral sentiments and habits of the people, have produced more instances of madness in France, than all their political calamities. The change in ancient customs and fixed habits, in old and established sentiments and opinions for speculative theories and dangerous innovations, has contributed to this. Religion now comes forward only as a formal usage on solemn occasions, and no longer affords her consolation to the afflicted, or hope to the desponding. Morality based on religion is no longer the guide of reason in the narrow and difficult path of life. A cold egotism has dried up all the sources of sentiment: there no longer exist domestic affections, respect, attachment, authority, or reciprocal dependences. Every one lives for himself; none is anxious to form those wise and salutary provisions which ought to connect the present age with those which are destined to follow it."

289. An enthusiastic, or a vehement and impassioned, mode of preaching, and declamations abounding with frightful pictures and condemnation, are not confined to any sect; and, in some countries, are as common amongst Romanists as among Protestants and protestant dissenters.—The itinerant missionaries of all sects—of Romanists as well as of Protestants—are remarkable for fanaticism; and for modes of preaching, more calculated to disorder the minds of persons, who are already suffering the ills of life, the depressing passions, bereavements of affection or of fortune, exhaustion of nervous power, and bodily disease, than to afford the consolations which religion is intended to administer in these and other circumstances of distress.

290. The question, which has been often agitated, as to the greater prevalence of insanity among Romanists and Protestants, may seem to bear upon this topic, but not so closely as it may at first appear; for, although mental disorders may be more frequent in the latter, than in the former, it by no means follows that religious feelings are the causes of this frequency, or that the numbers of the insane are greatly increased by cases of this kind. The number among Romanists may be as great as that in Protestants,—other circumstances compensating for the less influence of this cause in the former, than in the latter persuasion. That religious insanity, however, is much less common in Romanists than in Protestants, and especially protestant dissenters, cannot be doubted by any one whose sphere of observation has enabled him to form any opinion on the matter. Dr. HALLARAN (*Pract. Observ. on Insanity.* Cork, 1818, p. 32.) states, that in the Lunatic Asylum at Cork, in which the admissions of Romanists are about ten to one of Protestants, no instance has occurred, within his recollection, of mental derangement in the former from religious enthusiasm; but that several dissenters from the established church have been so affected. The reason of this difference is obvious. The ministers of the Romish church will not allow the minds of their flocks to distrust points of doctrine and discipline,—or to fall into these doubts, which distract the minds of those who are either wavering in their opinions or entertain entire liberty of conscience.

291. Whilst HALLARAN, GUISLAIN, LEUPOLDT, BURROWS, and others, contend for the greater prevalence of mental diseases in Protestants than in Romanists, JACOBI and CHIARUGGI believe that cases of religious insanity are also frequent in the latter. Dr. JACOBI remarks, that the character of religious madness in members of these two communities, and the manner of its accession, are for the most part different. In the lunatic asylums of Roman Catholic Germany, many of the inmates of the lower classes have become religiously mad, from the delusions of a wild and unregulated imagination, excited by superstitious phantasms, through neglect of the culture of the understanding, and the overpowering influence of sensual passions. Dr. PRICHARD has given a table from JACOBI, of the comparative prevalence of insanity in the Romanists and Protestants of the Prussian States on the Rhine; and it appears from it, that the proportion of lunatics in the former, compared with that in the latter, is as 11 to 10; and that the proportion is much higher among the Jews than in these persuasions. Still, this conveys no information as to the comparative prevalence of religious insanity among them.

292. Mr. TUKE's account of the Retreat, the asylum belonging to the Quakers or Friends, furnishes only 3 cases, out of 149, which could at all be ascribed to anxieties connected with religion; and in his list of causes of insanity amongst the inmates of this asylum, pride, ambition, jealousy, rage, debauchery, penury, or care produced by hardships, &c.—causes so productive of insanity in other institutions,—are not even mentioned. The exemption from these prevalent causes of mental disorder are attributable to the strictness of moral education and discipline, to the restraints imposed on the imagination and the indulgence of the passions, and to the absence of enthusiastic excitement on religious topics, in this sect. Still, insanity is as prevalent among Quakers, as among any other sect, relatively to their numbers,—owing, as above remarked (§ 253.), to the increased influence, in them, of hereditary predisposition.

293. From what has been now stated, it will appear that the frequency of religious insanity in different persuasions and sects will depend upon the excess of fervour characterising them. Exuberance of zeal on any subject soon passes on to madness in some constitutions; and on religion, unless tempered by a sound judgment, it is apt to degenerate into fanaticism, and thence into delirium which often becomes permanent. Excessive fervour, or enthusiasm, generally shows itself in religion, when any revolution of opinion or doctrine takes place; and when new lights and new sects arise amongst those who have

received a certain amount of education and religious instruction. Dr. Robertson (*Hist. of Charles V.* vol. ii.) has well remarked, that "when the human mind is roused by grand objects, and agitated by strong passions, its operations are apt to become irregular and extravagant. Upon any great revolution in religion, such irregularities abound most at that particular period, when men, having thrown off the authority of their ancient principles, do not yet fully comprehend the nature, or feel the obligation, of those new tenets which they have embraced. The mind in that situation, pushed forward with the boldness which prompted it to reject established opinions, and not guided by a clear knowledge of the system substituted in their place, disdains all restraint, and runs into wild notions, which often lead to scandalous and immoral conduct. Such was the effect in the first ages of Christianity, as well as at the era of the Reformation. The renunciation of the ancient faith, and ignorance of that which they had embraced in lieu of it, excited converts to acts more resembling insanity, than of that religion which inculcates the purest morality and government of our passions." — Dr. Burrows states, that he does not recollect an instance of insanity from religion, in any person steadfast to his ancient opinions. Wherever the disorder was suspected to proceed from this cause, it was clearly traced to the adoption of new tenets, which had not been comprehended, and found to originate during the conflict in deciding between opposite doctrines.

294. It must not be supposed, from what I have advanced, that the Christian religion is truly chargeable with causing insanity; it actually has an opposite tendency. Mistaken views, excessive fervour, unfounded fears, and various feelings arising from these sources, are the only causes of insanity in connection with religion. Amongst those who entertain just and sober opinions on religious topics, — who make Christian doctrines the basis of their morals, the governors of their passions, the soothers of their cares, and their hopes of futurity, — insanity rarely occurs. The moral causes of derangement, which would not fail of producing injurious effects on others, prove innocuous in them, for these causes would be met by controlling and calming considerations and sentiments, such as would deprive them of intensity or neutralise their effects. Truly religious sentiments and obligations soothe the more turbulent emotions, furnish consolations in afflictions, heal the wounded feelings, administer hopes to the desponding, and arrest the hands of violence and of despair.

295. In considering how far insanity may have arisen from mistaken views, or ill-regulated zeal, in religion, the influence of sounder Christian doctrines in preventing its occurrence from other moral causes ought not to be overlooked; but this beneficial influence is too often unheeded, from being seldom brought to the notice of the physician, or from being altogether concealed in the breasts of those who have experienced it, whilst the origin of mental disease in disordered religious feelings is obtruded upon his attention. If the data could be procured, I believe, that it would be certainly found that the very great majority of those who have committed suicide in states of mind which at least very nearly approach, if they do not altogether amount to, insanity, actually either have been of no religion at all, or have entertained a very imperfect and inadequate sense of it; and that religious obligations have often suppressed suggestions of suicide, which would certainly have been committed if these had not been entertained. And further, I believe, that a very large proportion of those who become insane, especially amongst the lowest and most ignorant classes, have fallen into this state from the scope given to their temper and passions, and from other mental causes, deprived of that salutary control, and of those consolations, furnished by the beneficent doctrines of Christianity. The tendency of Cowper to mental derangement was long opposed by the influence of true religious principles; and, in later life, a sense of his duties and obligations arrested his hand in the act of suicide.

296. *B.* Physical Causes of Insanity. — The *physical causes* of insanity may be divided into — 1st, Those which affect the encephalon chiefly and immediately; 2dly, Those which exhaust organic nervous power, and disorder the general organic sensibility; 3dly, Those which act upon remote organs or parts, with which the brain is disposed to sympathise. — Under the head of physical causes, M. Esquirol has arranged *hereditary predisposition*. In treating of the causes of insanity, this should be viewed apart from the exciting physical causes; for, although it often appears to occasion insanity, without any other circumstance being recognised to develop the predisposition, and although it is strictly physical, it still requires, from its nature and influence, an early and separate consideration (§ 251.).

297. *a.* Of *the causes which more directly affect the encephalon*, — *α. Insolation, sun-stroke*, and exposure of the head to great heat, as to the fires of forges, &c., deserve a passing notice. M. Esquirol has observed considerable influence from the last of these; and I have known several instances of exposure to the heat of the sun in warm climates, and in hot days in temperate countries, having developed an attack of mania. Cases of this kind partake much of the character of phrenitis, and are actually such in most cases, especially at their commencement; whilst, in others, more or less of congestion takes place, or follows a state of inflammatory action. It is chiefly where a marked predisposition has existed, or moral causes have cooperated with this, that mental disorder is developed, or persists for a considerable period. In some instances, exposure to the sun's rays first produces an epileptic seizure; the derangement of mind either immediately following it, or appearing after several recurrences. These cases more obviously proceed, at first, from the congestion, or vascular turgescence, of the brain or of its membranes, caused by the solar rays. Exposure to the heat of *charcoal fires* has also been observed to cause insanity; the fumes of these fires probably contributing to these injurious effects. The liability of cooks to mental disorder, which has been remarked on the Continent especially, is probably attributable to this cause.

298. *β. Frequent or habitual determinations of blood to the head*, and *congestions of the brain and its membranes*, are amongst the most common physical causes of insanity, especially when an hereditary disposition to it exists; but, frequently, some fully developed or specific organic malady

of the brain appears before the effect upon the mind is manifested, — especially *apoplexy* and *paralysis*. In these latter cases, softening of a portion of the brain, or hæmorrhage in some part of it, or both lesions, with various attendant changes, are the more immediate effects, and upon these the mental disorder is only contingent in some instances. When mental disease follows apoplexy, some form or other of paralysis is often associated with it. The varieties of mental disorder consequent upon *apoplexy*, or upon *paralysis*, or upon both, are chiefly the several grades of dementia, and forms of partial insanity; but any other variety may also proceed from them. (See art. Apoplexy, § 52. *et passim.*)

299. γ. *Epileptic* and *convulsive affections* are, perhaps, more frequently productive of insanity, and especially of the several grades of dementia (§ 155, 156.), than any other disease, unless, perhaps, *apoplexy* and *paralysis*. M. Esquirol states, that of 300 epileptics in the Salpêtrière more than one half are insane. It may be supposed that the influence of epilepsy in causing insanity depends chiefly upon congestion of blood on the brain, or vascular determination to it; but this inference may be only partially correct; for, even admitting that these lesions of the cerebral circulation are present in many epileptic cases, it does not follow that they exist in all of them. I believe that it will be found, that when epilepsy is connected with, or depends upon, a deficiency of blood, and great impairment of nervous power (see art. Epilepsy, § 27.), that it is more apt to be followed by insanity than when attended by either congestion, or determination of blood to the brain. M. Esquirol remarks that, although epilepsy and convulsions are often causes of insanity, especially of furious mania and dementia, that *vertigo* still more frequently precedes, and is more destructive to the mental powers than they. I believe that vertigo more frequently proceeds from an impaired circulation in the brain, conjoined probably with weakened organic nervous energy of this organ, than from opposite states of the circulating and nervous system. — *Cataleptic* and *ecstatic* affections, and *somnambulism*, may also lapse into mental derangement; or, in other terms, the states of nervous influence and of cerebral circulation, causing these affections, may be only early stages or grades of the same physical disorder of which insanity is the consequence.

300. δ. *The transference or metastasis of disease to the encephalon*, is a not infrequent cause of insanity, especially where a predisposition to it exists. The sudden disappearance, or the suppression, of cutaneous eruptions, of accustomed discharges and evacuations, and of certain painful or constitutional maladies, has often been followed by mental disease. Cases illustrative of the production of inflammatory and other diseases of the brain, and of the various forms of insanity, from these causes, abound in all practical medical works. The suppression of herpes, of scabies, and of other chronic cutaneous eruptions, — of various discharges, as leucorrhœa, chronic diarrhœa, &c., — of hæmorrhagic evacuations, as epistaxis, hæmorrhoids, menorrhagia, — and of gout and rheumatism, — has frequently been followed by insanity, and especially by mania, and melancholia, either in their simple forms, or complicated with paralysis or epilepsy. Where the mental disorder thus supervenes, distinct evidence of acute or subacute inflammation of the brain or of its membranes, or of both, is often evinced for some time before the mind becomes disordered.

301. ε. *Inflammatory and other diseases of the brain* are frequently followed by mental derangement. The delirium symptomatic of these maladies, and of fever with predominant affection of the brain, may subside into one or other of the forms of partial or general insanity; and the various organic lesions occurring in the encephalon and its membranes may be attended, at an early stage, with more or less mental disorder; or, after having given rise to epilepsy, paralysis, or apoplexy, may be followed by such disorder. In such cases, however, the mental affection is to be viewed rather as a contingency, than as a necessary consequence of the organic disease.

302. ζ. *Injuries of the head* are sometimes productive of insanity; owing chiefly to chronic or slow inflammatory action, and its consequences in the brain or membranes. In some cases, acute disease, attended by delirium, is the first effect; but, consequent upon this, any grade of chronic insanity may appear. Occasionally, even, the mental affection does not occur until years have elapsed from the receipt of the injury; and it then may present every grade of severity, and may even be associated with epilepsy or paralysis. During the long interval that may thus elapse, various symptoms, referrible to the encephalon, are generally complained of, and are sometimes so manifest to the physician, as to lead him to dread the impending calamity, and to employ means, which as often fail as succeed in averting it. Dr. Prichard remarks, that there are instances in which a slight peculiarity of character, not amounting to insanity, has remained long, and perhaps through the life of the individual, who has sustained a severe injury of the head. Sometimes this amounts to a kind of moral insanity; the temper being more irritable, and the feelings less under restraint, than formerly. In other instances, there have been greater energy and activity, more of excitement in the general character, which have been thought a change for the better, rather than a morbid alteration. Of this, two remarkable cases have come under my own observation. Van Swieten, Haller, and others have adduced instances of congenital and puerile imbecility having been removed by injuries on the head; and Dr. Prichard mentions a family, consisting of three boys, all idiots, one of whom, having received a severe injury on the head, had his faculties restored, and became a professional man of good talents.

303. *b. Whatever greatly exhausts organic nervous power*, both predisposes to, and directly occasions, insanity. — *a.* Many, however, of those causes, which thus affect nervous energy, favour congestion on the brain, and occasion disease of other vital organs, tending to disorder the functions of the brain sympathetically. Of these, the most influential are masturbation and libertinism, or sexual excesses, sensuality in all its forms, and inordinate indulgence in the use of intoxicating substances and stimulants. The baneful influence of the *first* of these causes is very much greater, in both sexes, than is usually supposed; and is, I believe, a growing evil, with the diffusion of luxury, of precocious knowledge, and of the vices

of civilisation. It is even more prevalent in the female, than in the male sex; and in the former it usually occasions various disorders connected with the sexual organs,—as leucorrhœa, displacement of the uterus; difficult, or disordered, or suppressed, or profuse menstruation; both regular and irregular hysteria, catalepsy, extasis, vertigo, various states of disordered sensibility, &c., — before it gives rise to mental disorder. In both sexes, epilepsy often precedes insanity from this cause; and either it or general paralysis often complicates the advanced progress of the mental disorder, when thus occasioned. Melancholia, the several grades of dementia, especially imbecility and monomania, are the more frequent forms of derangement proceeding from a vice, which not only prostrates the physical powers, but also impairs the intellects, debases the moral affections, and altogether degrades the individual in the scale of social existence, even when manifest insanity does not arise from it. Sexual excesses, and libertinism in persons predisposed, hereditarily or otherwise, have a similar effect to the former cause, although neither so frequently nor so certainly; the mental disorder generally assuming the same forms and morbid associations as have just been mentioned.

304. *β. Intoxicating substances and stimulants* are causes of mental disorders in most countries; but they are among the most influential of all the exciting causes in the lower classes, particularly in the United States of America, in Great Britain and Ireland, and in Germany. In France, Italy, and Spain, this vice is much less frequent. Spirituous liquors are the most generally indulged in; and are the most injurious in their effects, not only on the nervous system, but also upon the digestive and excreting organs. A large proportion of the admissions into pauper lunatic asylums arise from this cause, especially in large cities and manufacturing towns and districts. Mania, monomania, and melancholia most frequently proceed from the abuse of intoxicating liquors; and the cases which are thus caused, are amongst those which are oftenest cured — at least, for a time. The removal of the cause, and the use of sedative means, generally cure the attack: but relapses or recurrences are more frequent in these, than in any other class of cases.

305. The excessive use of opium is as injurious to the nervous energies, and to the mental powers, as addiction to spirituous liquors; but the ill effects resulting from it on the mind, are not often observed in this country. — I have known several instances, all of them females, of the acetate of morphia having been used, instead of opium, as a restorative and intoxicating agent. It was ultimately more or less injurious in all; and in one, partial insanity, with suggestions of suicide, appeared, — but probably other causes contributed to the morbid effect.

306. *γ.* The abuses of *mercurials*, and particularly of *calomel* as a common or frequent purgative, has, in several instances in which I have been consulted, been productive, first of depression of the nervous power, and of a morbidly increased state of the general sensibility, and subsequently of melancholia and other forms of monomania. A surgeon, a pupil of the late Dr. Currie, was in the habit of taking large doses of calomel, at least twice, but more frequently oftener, in the week. He believed himself subject to disease of the liver, resorted to this medicine when he found his spirits greatly depressed, and considered that he was better the day after taking it. He persisted in the frequent use of calomel, and became more and more nervous and hypochondriacal. He was afterwards melancholic, entertained mistaken views of religion, and attempted suicide, which he accomplished in a subsequent attempt. — The daughter of a clergyman in this city was attended by this surgeon, and had very frequently taken large doses of calomel. Her health and spirits had become remarkably impaired, and her intellects disordered. There was no hereditary predisposition to insanity in either side of the family. She had been fond of company and amusements; but was melancholic, physically out of health, tormented by the most distressing religious fears, and refused being seen by her relatives and former friends, when I was directed to visit her. Her despondency, mental misery, and religious delusions were remarkable; and she had frequently contemplated suicide, in order to terminate her suffering. She completely recovered under a restorative treatment, aided by change of scene and of air, and by suitable moral management.

307. *δ. The too frequent or excessive use of colchicum*, for the removal, suppression, or prevention of gout, has given rise to insanity in three instances in which I was consulted. In one of these, melancholia was the more immediate disorder of the mind; in the others, incoherence and imbecility, with illusions, were the consequences. — All powerful *depressants*, and even *cold*, either excessive in grade, or prolonged in its operation, may occasion insanity, by their operation on the nervous power.

308. *ε. Excessive or prolonged lactation*, relatively to the patient's strength, profuse evacuations, particularly leucorrhœa, frequent menorrhagia, profuse hæmorrhoidal discharges, &c., have also induced melancholia, and other partial forms of insanity, and even imbecility, or more complete dementia, chiefly by exhausting the vital powers, especially of the nervous system. It will afterwards be shown, that *puerperal insanity* is occasioned partly by this cause, or rather by the evacuations consequent upon parturition, in connection with previous suffering, and increased susceptibility of the nervous system. Something also may be imputed to the altered state of the general circulation, and of the condition of the uterine organs.

309. *c. Diseases of Organs with which the Brain more or less sympathises*, not infrequently cause insanity, when a predisposition to it already exists. So intimately associated in function are all the organs of the body, through the numerous bonds of union furnished by the organic nervous and vascular systems, that serious disease seldom exists in either, without the functions of one or more of the others being remarkably disturbed: and when visceral disease occurs in a person who has an hereditary or an acquired predisposition to mental disorder, the former is often the cause of the development of the latter; various other circumstances, however, moral and physical, often co-operating with this cause, in the production of the morbid effect upon the mind. — Of this class of physical causes, habitual constipation, inflammatory irritation of the gastro-intestinal mucous surface, diseases of the heart and lungs, functional

disorders and organic lesions of the uterus, and diseases of the biliary and urinary organs, are the most important. It is chiefly when these visceral maladies appear in an obscure and insidious manner, and proceed slowly, that the functions of the brain become disordered in a chronic form.

310. *α.* Without attributing nearly so much influence, as M. Broussais has done, to inflammatory irritation of the *gastro-intestinal mucous surface*, it cannot be denied that its pre-existence is of considerable importance in the production of the mental disorder. But it is very seldom the sole physical cause in these cases; most commonly, exhaustion or depression of the organic nervous influence co-operating with it in producing the effect upon the mind. The disorder of the digestive organs is generally caused, by the excessive use of stimulating and indigestible food, among the opulent; and by constipation, intemperance, unwholesome food, and by cold and want, among the lower classes. In these cases, hypochondriasis, or hypochondriacal melancholia, first appear; and various forms of general insanity supervene.

311. *β.* Severe functional and organic disease of the *heart* or *lungs* may excite insanity in the predisposed, owing to disorder of the circulation in the brain, consequent upon interruptions of it in these organs. — When mental derangement follows diseases of the *biliary* or of the *urinary organs*, it may proceed more immediately from the influence on the brain of the excrementitial matters accumulated in the blood, in consequence of the impaired or disordered function of these organs.

312. *γ.* Of the operation of the functional and organic affections of the *uterine organs*, but little need be here added to what has already been observed. In these cases, the sympathetic effect takes place, most probably, by the propagation, to the spinal cord and brain, of irritation originating in the sexual apparatus; and the mental disorder is generally preceded and attended by one or more of the numerous forms of hysteria, or by epilepsy, and sometimes also by hypochondriasis, or great lowness of spirits. This is especially the case when the catamenia are difficult or suppressed. In many cases, not only uterine disorder, but also gastro-intestinal irritation, is accessory to the causation of the mental disease.

313. In considering the operation of all these physical causes, it should not be overlooked, that it is often extremely difficult to determine, whether the disorder originates in the brain — the other organs sympathising with it, — or whether the disturbance of the mental powers is altogether owing to disease of viscera remote from the encephalon. But, however difficult it may be, an attentive examination of the history and existing symptoms of the case should be instituted, to the determining of this point; as much of the success of treatment will depend upon correct views regarding it.

314. *δ.* When organic nervous or vital power is much depressed, especially in respect of the digestive and excretive functions, *accumulations of morbid secretions, and collections of fæcal matters*, are liable to form in the intestinal canal, and particularly in the *cæcum* and *colon*. These dilate, displace, irritate, and obstruct the bowels; occasioning flatulent distension, spasm of the muscular coats, and various disorders of the whole tube, as well as of the collatitious viscera. These morbid accumulations are apt to occur even in persons who suppose their bowels perfectly open and regular; and they more certainly take place in those who are habitually costive or constipated. The effects, however, of collections of morbid secretions in the bowels, — particularly in the large bowels, — are not limited to these, or even to the adjoining viscera; although, if even thus limited, they would often be sufficient to excite, by the intimate sympathy existing between the digestive organs and the brain, functional disorder of the latter, especially in persons already disposed to such disorder. But there is every reason to believe, that when morbid or fæcal matters accumulate in the intestines, either with or without constipation, the chyle thereby becomes more or less impure or contaminated, and that a portion of these matters is absorbed into the circulation, the blood being consequently altered, and a state of general cachexia being thus produced. Where the predisposition to insanity already exists, the morbid materials conveyed into the blood will be often sufficient to derange the functions of the brain; and, not infrequently, this consecutive derangement will not be limited to these functions, but will extend to several others.

315. The sympathetic influence of the digestive organs on the brain, in connection with the deterioration of the chyle, and the absorption of excrementitious matters from the bowels into the blood, will in this manner occasion hypochondriasis, melancholia, partial and general insanity, and, ultimately, even some of the complications which these occasionally present. The displacements and dilatations of the colon so often observed in melancholia, and sometimes also in other disorders of mind, most probably result from frequent or habitual constipation, even previously to the appearance of mental derangement. And the inflammatory irritation of the gastro-intestinal surface, already noticed (§ 310.) as causing and attending many cases of insanity, is probably the more immediate effect of the impaired energy of the digestive canal, and of the accumulation in it of morbid matters; the consequences as respects the chyle and the blood, just contended for, increasing the effects upon the functions of the brain. The influence of constipation, or even of habitual costiveness, in causing insanity, and the good effects of powerful purgatives in the treatment of it, were well known to the ancients, and to most of the older writers; and, though fully recognised in this country, have been imperfectly estimated on the Continent in recent times, and even erroneously viewed by many, and particularly by Broussais and his disciples.

316. *ε.* Besides the above physical causes, *pregnancy*, the *accumulation* of morbid matters in the intestinal canal, and *of bile* in the biliary apparatus, the presence of *worms in the bowels*, *hypochondriasis*, and *hysteria*, frequently give rise to insanity. The abuse of medicines, and of all substances which act powerfully on the nervous system, and especially of green tea or of coffee, is occasionally, also, a cause of mental disorder.

317. *ζ.* M. Esquirol (*Mal. Ment.* t. i. p. 64., et t. ii. p. 682.) has given the following *tables of the causes of insanity*; — the *first* comprising only the physical causes among female cases; the *second* embracing both physical and moral causes in cases of both sexes at Charenton.

Physical Causes.	Salpêtrière.	M. Esquirol's Establishment.
Hereditary predisposition - -	105	150

									1375

318. M. Esquirol remarks, that the causes were often ascertained with much difficulty; as the patients themselves were generally incapable of assigning them, and the friends could not always do so — at least, with any degree of precision. It is probable, however, that two or more causes were concerned in producing the effect, and that various circumstances were omitted; he considers that hereditary predisposition is much more frequent than stated in the above table. Under the head of domestic distresses, are included all the moral affections which are called into action in the interior of a family. The political changes in Paris, in 1830, gave rise to the cases from this cause, and to those produced by frights.

319. *n. Sol-lunar influence* was very generally supposed to excite or to favour the appearance of insanity, as well as to cause exacerbations of the malady. M. Esquirol could not verify this opinion by the results of his experience. It is probable, however, that electrical states of the air, or sudden vicissitudes of the atmospheric electricity, in connection with similar changes in the electrical currents through the body, have some influence on this malady. The effects of excessive cold and of great heat in causing madness, and the excitement produced in lunatics by atmospheric commotions, are indications of this influence. However this may be, there can be no doubt of marsh miasmata being a not uncommon cause of insanity, and especially of melancholia and dementia.

320. *C.* Various circumstances arising out of the manners and social and political states of a community may increase the frequency, or contribute to the production, of insanity. Still, these states are more or less connected with the affections of the mind and the other moral causes, or are resolvable into them. — *a.* The social conditions resulting from prevailing modes of education have been considered by M. Esquirol as most influential in increasing the numbers of the insane. Too much care is taken to cultivate the mind, not considering that the affections of the heart require equal care. In all classes, an education is bestowed upon the young, above what is suitable and proper to their station in society; and hence sentiments of ambition, and of discontent with their condition, are instilled into their minds from childhood. This early and ambitious education raises the mind of the young above, and too often in opposition to, the experience of their parents; and hence the opinions of the latter are despised or neglected. A person who has not been duly controlled in childhood is ill able to endure the vicissitudes and reverses to which an active life exposes him in the present state of society, — his passions being thereby deprived of a salutary curb, and his reason of its surest props, insanity often follows upon the least adversity. The manner of living in the easier classes of society,—the passion for dress, for exciting romances, for intrigue, for frivolities and amusements, — engender a constant thirst for excitement, and increase the frequency of nervous complaints and mental disorders. The vices, and the miseries and privations consequent on these vices, in the lower grades of society, have a no less marked influence in causing the latter of these effects more especially.

321. *b.* In country districts, the prevailing passions are less turbulent and exciting than in cities and large towns. Love, anger, and domestic contrarieties are the most frequent moral causes of mental disorder in the former; whilst, in the latter, ambitious views, speculations, disappointed hopes, reverses of fortune, excessive mental labour, watchings and late hours, greater depravation of manners, and more vicious indulgences, are added to these; and, consequently, insanity is more prevalent in populous, commercial, and manufacturing towns, than in rural places. In proportion as the latter causes are prevalent in any community, and are aided by a more or less general propensity to drunkenness, or to libertinism, or by the vices of education, and of conduct in the richer classes, and by the want of both in the lower orders, so do the disorders of the mind become more frequent.

322. *c.* Even *forms of government* have considerable influence in contributing to this result. There is not the least doubt of the ill effects of a too great freedom of public opinion and acts, and of public writing and speaking, upon mental sanity. With the freedom of opinion, and the latitude allowed to the expression of it, without re-

gard to the feelings and the interests of individuals, or to the morals and sympathies of the community, those emotions which most seriously disturb the mind, are brought into the most violent and distressing action, and the calm dictates of reason thereby overthrown. The political strifes, the popular elections, the borough and parish contentions, in this country, and in the United States of North America, furnish sufficient proofs, to the candid mind, of the truth of this position. The exciting, the contaminating, and the disgusting occurrences and circumstances, which daily, and even hourly, are placed before all classes in society, in most exuberant variety and particularity of detail, — the moral poison with which the whole is garnished, in the lowest, the cheapest, and the most diffusible of these vehicles of abominations, and of mental infection, — the liberty which contaminates the innocent, demoralises the public, injures the feelings, and benefits only the worthless and the base, — all tend to the consummation of the injurious effect upon the mental health of the community — to the increase of crime, of madness, and of suicide.

> "Here, by the bonds of nature feebly held,
> Minds combat minds, repelling and repell'd:
> Ferments arise, imprison'd factions roar,
> Repress'd Ambition struggles round her shore:
> Till, overwrought, the general system feels
> Its motion stop, or frenzy fire the wheels."

323. *d. Political commotions*, by exciting revenge, and the more violent passions of the public, by fomenting ambition, by rousing to intellectual exertions, and by overturning fortunes and the established order of things, have a marked influence in augmenting the frequency of insanity. The frights, terrors, outrages, distresses, and losses of fortunes, of friends, of honour, &c., consequent upon foreign invasions, sieges, and civil and domestic wars, are most fruitful causes of derangement on these occasions. Numerous proofs of this have been adduced by the French and German writers since the last war. Revolutions moreover do not only greatly increase the numbers of the insane, but also impart certain characters to the prevailing mental disorders. M. Esquirol observes, that, when the ancient monarchy was destroyed, many became mad from the loss of fortune and friends, and from the frights and terror caused by the consequent anarchy. When the Pope came to France, religious insanity was most frequent; and when Napoleon made princes and kings, insanity from ambition and pride was frequent, and kings and queens were numerous amongst lunatics. Religious revolutions have a similar influence; and even the prevailing ideas called into existence or activity by these revolutions, by great political events, and by popular commotions, contribute both to the frequency, and to the character, of this disorder. The prevalence and features of madness, during the Crusades, and for long afterwards; during the Reformation, in Germany, the Low Countries, and Great Britain; and during the civil wars, and the temporary domination of puritanism, under the long parliament and Cromwell; are illustrations of what I have just advanced.

324. *e.* M. Esquirol states, that a sedentary, indolent, or inactive mode of life favours the occurrence of insanity; and that persons who have been accustomed to a very active life, as merchants, traders, professional men, and soldiers who have led an irregular and an eventful life, are liable to this malady when they settle to the enjoyment of wealth and splendour.

325. *f.* Another circumstance of great importance presents itself in the relative frequency of insanity in the *married* and *single*. The following *Table* contains the results furnished on this subject by Esquirol, Desportes, Jacobi, and Prichard: —

	Desportes.		Jacobi.		Esquirol.	
					Charenton.	
	Salpêtrière. Females.	*Bicêtre.* Males.	Females.	Males.	Females	Males.
Unmarried - -	980	492	599	974	193	505
Married - - -	397	201	156	176	363	387
Widowers and Widows	291	59	80	30	69	40

The differences in these results depend much upon the classes of persons admitted into the institutions from which these results are obtained, and upon the limitations observed as to admission. Still, enough is proved by them to suggest important considerations connected with the hygiene and prophylaxis of insanity. With respect to the results which are here adduced, Dr. Prichard observes, that, as it appears probable that celibacy tends to augment the numbers of lunatics, an inquiry is suggested as to the manner in which this result ensues. Is it through the restraints which the condition of celibacy imposes, or through the vices to which unmarried persons are more frequently abandoned? M. Esquirol is of opinion, that, where one case of insanity arises from the former cause, a hundred result from the latter. A case occurred to me some years ago, of a well-educated man, hereditarily disposed to insanity, who, after long periods of continence, experienced symptoms premonitory of mania. He married soon after, having been under my care. Several years have since elapsed, without any indication of mental disorder having appeared. Persons happily married, generally lead more regular lives, in all respects, than the unmarried, and are more fixed in their pursuits and employments. In many other respects, also, the condition of married persons is much less favourable to the excitement of madness than that of celibacy.

326. In taking a survey of the feelings, the emotions, and the passions, as well as of the numerous circumstances connected with the social states, productive of insanity, the conclusion is irresistible, that the diminution of its frequency depends more upon the constitution of individual minds, proceeding from habitual control, and from a due exercise of moral and religious principles and obligations, than upon all other circumstances combined.

> "Vain, very vain, the weary search to find
> That bliss which only centres in the mind.
> In every government, though terrors reign,
> Though tyrant kings and tyrant laws restrain,
> How small, of all that human hearts endure,
> That part which laws or kings can cause or cure!
> Still to ourselves in every place consign'd,
> Our own felicity we make or find:
> With secret course, which no loud storms annoy,
> Glides the smooth current of domestic joy.
> The lifted axe, the agonising wheel,
> Luke's iron crown, and Damien's bed of steel,
> To men remote from power, but rarely known,
> Leave reason, faith, and conscience, all our own."

327. VII. Of the Physiological Pathology of Insanity.—i. Remarks on Mind and Organisation. — *A. Of the Scope of these Inquiries.* — The human frame respires, digests, thinks, wills, and acts: in a few hours afterwards, and often without any obvious cause, it performs none of these functions; and, in a few hours more, it falls into dissolution. These phenomena are familiarly known to us; and, although they are considered by all to form a part of the established order of the universe, yet they must have engaged the reasoning powers of man from an early period of his social history, and have been amongst the earliest subjects of philosophic discussion. As the cause of these occurrences is necessarily embraced by speculations as to the origin and nature of mental as well as of corporeal disease, so it may be supposed to have always been a matter of deep reflection to physicians from the earliest ages. The constitution of the human mind leads it to search after first principles, in order to explain the operations continually taking place within and around it; and the hopes of obtaining information respecting the source of the deranged states to which itself, as well as its associated frame, is liable, and even of discovering the nature of its own origin and connections, seriously interest a class of inquirers whose occupation naturally suggests these considerations. Yet, although these inquiries more immediately concern the practitioner of medicine, especially as respects the more obvious changes which mind and its allied matter present to his view, still the intimate relations of both the one and the other, the nature of the connection subsisting between both, and the more removed links of the chain which binds them to their first cause, and to the universal system of nature, are no farther disclosed to him, than to any one else who patiently scrutinises the objects which come under his view. As man did not create himself, so neither can the faculties with which he is endowed inform him, of themselves, even plausibly, either as to their own formation, or as to the original production of the frame which manifests them, or as to the connections which the one has with the other, or even regarding the ultimate cause and circumstances of the apparent dissolution of both. How can the machine explain the principles of its peculiar construction, or demonstrate the views which actuated its maker? How can we expect the powers of mind, which cannot be supposed to have been formed without a cause, to acquaint themselves of their own modes of being anterior to their present state of existence? and how much less can they furnish information respecting the nature of that cause from which they necessarily derived their origin! They may, however, enable their possessor to recognise the phenomena which take place within and around him. They can mark the modifications and the sequence of operations characterising their own constitution, and the properties of substances by which they are surrounded; and they may even expatiate beyond the objects of sense: still the powers of human intellect, exalted as they are, can neither, through their own instrumentality, arrive at a knowledge of their own intimate nature, or of the manner in which they first came into existence; nor explain, satisfactorily, the kind of connection which they hold with their first cause, on the one hand, or with the matter with which they are associated, on the other. Notwithstanding that the field is thus narrowed, it will be still found sufficiently extensive for exact research and profitable cultivation.

328. Although speculations respecting the nature and the material alliances of mind are sufficiently unprofitable, when directed to such topics as the above; yet, as they disclose points of great utility, when they are pursued in a different direction, they should not be altogether discouraged. It is to the medical philosopher that these points are especially manifested, and hence he becomes more particularly interested by discussions in which they are in any way involved. But, as his daily researches and occupations are apt insensibly to bias the opinions he may form as to those subjects, so his inquiries will often betray, upon strict examination, more of the *idola tribûs*, than of exact deduction. Besides this important source of error, there are others, in which he partakes in common with all inquirers. How very few physiologists are truly sound reasoners and exact philosophers! How often are the first requisites of valid argument overlooked, even at the outset of our researches after truth! How few, among those who peruse the discussions to which these researches lead, discover the sources of error! and how many are carried along with the sophistries which flow from these sources!

329. These objections, although strictly applicable to those topics to which I have alluded as being placed above the reach of our faculties, have, however, no reference to the correct observation of the healthy manifestations, and of the derangements of mind. The former topics, at the best, can be considered, from their very abstract, or rather, inscrutable, nature, as matters of curious speculation; the latter, being objects of consciousness and experience, are the true subjects of philosophy, and, from their involving the welfare and existence of human beings, are matters of practical importance in the scientific prosecution of our profession.

330. As our knowledge respecting life and mind can be derived only from a careful examination of the phenomena which organised bodies present, — for we have no experience of the former unassociated with the latter, — so our acquaintance with the manifestations of mind can be obtained only by an intimate investigation of the nervous system, and of its functions, in the higher animals and in man, and by attending to the objects of our consciousness. Of all the opinions which have been entertained as to the cause of vital phenomena, there is none in which these phenomena are not ultimately ascribed to one or other of two causes; namely, either to a certain organism of the materials of which the visible structure of the animal is composed, or to a principle totally distinct from, yet most intimately allied or associated with, it; which principle seems to have suggested itself to all mankind, and to have received a distinct appellation. Opinions have necessarily been similarly divided as to the cause and mode of existence of the mental manifestations; — the one being, that they result from the organisation of the brain and nervous system; the other being, that, like vitality, they are distinct from the structures with which they are associated, and which are the instruments only of their operation. Hence, physiologists are divided on this subject into two classes; — the

one ascribing all vital and mental phenomena to organisation; the other attributing it to a distinct principle — to vitality — allied to organisation, in which state of alliance only is it subjected to observation, and made an object of investigation and of experience. Accordingly, the one class believes that the range and power of intellect entirely result from organisation; the other considers that organisation is only the medium or instrument of mental manifestation, whilst it continues to be actuated by life — that the powers of mind are the result of the vital endowment of the brain. Although opinions on this subject may be thus classed, according to their general and fundamental principles, yet they vary remarkably in their subordinate particulars — owing chiefly to their discursions beyond the range of consciousness and observation, and into the regions of imagination and wild speculation.

331. The functions of the brain, in connection with the doctrine of life, have attracted the attention of philosophers from a very early period; and, during the last century, they have engaged the researches of some of the most acute inquirers who have "interrogated nature." The progress of our knowledge, however, in this very interesting but most difficult field has not been equal to the growing zeal with which it has been cultivated. This want of success is entirely owing to the circumstances already alluded to, — to the obstacles which beset us when entering upon investigations in which we encounter the mysterious union of mind with matter, and which relate to the more intimate states of both, and to their mutual influences in different and often in contradictory circumstances and aspects. The operations of the nervous system, possessing, as it does, so extended a connection with the mental powers on the one hand, and with the corporeal functions on the other, and reciprocally receiving and communicating influence during health and disease, could not be accurately traced, even in the more evident phenomena, without some reference to the sources and relations of vital and mental manifestations; and hence have sprung up various and conflicting hypotheses, which have demonstrated little beyond the narrow limits of our knowledge and of our powers. These humiliating considerations obtrude themselves, when we view the numerous speculations which have been entertained respecting life and organisation, and their relations to mental manifestation, from the earlier dawn of philosophy to the present time, when we consider the conclusions to which many of them lead, and when we reflect upon the small progress that has actually been made in this department of knowledge. How little has been added even to the physiological part of these researches, notwithstanding the self-felicitations of some recent inquirers, since the writings of Galen! how much of what has been supposed to have been discovered, still remains open to contradiction, cavil, and doubt! and what has the science of mind gained from the works of their modern followers, in addition to what appears in the discordant theories of Plato, Aristotle, and Epicurus! It cannot be a matter of surprise that human intellect has been tossed for many ages upon an ocean of uncertainty respecting its nature and relations, seeing that it was never guided by any sound principle of philosophising, by which it might have been navigated into a safe haven. Until the philosophy of Bacon extended, in this country, its influence to the science of mind, but little care was taken to attend closely to the intimations of consciousness, and to investigate the nature, the extent, and the mutual relations of our faculties. The more precise attention which has recently been paid by some writers in this country to the objects of consciousness, and to the origin and history of our ideas, whether those which are derived from our senses, or those resulting from reflection, will serve to guide our speculations to conclusions more correct, and certainly more ennobling, than many of those are capable of accomplishing, that have been entertained in modern times.

332. *B. The opinions of the Ancients respecting mind and the vital phenomena* were sufficiently vague; and yet, when strictly examined, not much more so than most of the views promulgated in modern times. Ψυχη, *anima*, vital principle, or soul, according to some, were employed by them to express the cause of the vital actions; the term ζωη designating the effect of that cause. Democritus, Epicurus, and the Stoics considered the soul to be corporeal, or material; but differed as to the matter constituting it. Hippo maintained that it was water; Democritus, that it was fire; Heraclitus, that it was a vapour, or exhalation; and the Stoics, that it was warm or ignited air. Of those who believed the soul to be incorporeal, some considered it mortal, and others that it was immortal. Thales said that it was the origin of motion, and always in motion; Pythagoras, that it was a self-moving monad; Plato, that it was conceivable only by the understanding; and Aristotle, that it was the first εντελεχεια, or element bestowing on others the possibility of life. The Manicheans imagined that there is but one universal soul, which is distributed in portions to all bodies. Plato and others maintained the existence of an universal soul, by whose influence all things existed; but that living creatures possessed separate souls, which have a threefold constitution, — reason, placed in the head as in a citadel, passion in the chest, and desire in the abdomen. The Greek philosophers, who taught the immortality of the soul, generally believed in its transmigration. Galen, adopting the doctrine of Plato, considered the soul to possess three faculties, located in the three cavities of the body, — a ruling or rational one in the head, a vital one in the thorax, and a natural one in the abdomen. These distinctions were long entertained in medicine, together with the subordinate faculties which Galen supposed to preside over particular organs, and which Harvey denominated *sensus proprii*, and Blumenbach, more recently, *vitæ propriæ*.

333. The Greeks, who believed in a vital principle, had long been accustomed to arrange its energies under different heads, as the φρην and the ϑυμος; the former implying the intellectual and voluntary functions, the latter the involuntary, which originate either in sensation or instinct. Some of their authors arranged the faculties of life under three heads, — the νους, φρην, and ϑυμος; the first comprising the intellectual and rational powers, the second those operations supposed to belong to the viscera of the thorax, and the third those spontaneous functions termed organic or vegetative, belonging to the organs of nutrition

placed in the abdomen. The Latin writers employed the words *mens, animus*, and *anima* in senses nearly corresponding with those attached to the terms used by the Greeks; although LUCRETIUS, in his developement of the Epicurean philosophy, is by no means precise in the use of them, and more generally employs *mens* and *animus* as synonymous terms, or very nearly as such.

334. EPICURUS, according to the explanations of LUCRETIUS, was the first who constructed a system of materialism. He ascribed organisation, and the vital and mental phenomena displayed by it, to combinations of ultimate and invisible atoms, possessed of various shapes. He does not attempt to show how these shapes co-operate to form either an animal or a plant. He merely asserts that the elements produce both from a combination of atoms; and that, in his time, many animals were formed, by showers and sunshine, out of the mud. This is one of the modes of spontaneous evolution contended for by some of the modern German physiologists. It being impossible to explain the manifestations of organisation and mind, and, indeed, of the universe, by means of the doctrine of atoms alone, a being of superior power was introduced, and invested with great authority. This being, who belonged neither to atoms, nor to elements, nor to any of their properties, was called Nature. "Her existence," observes Dr. BARCLAY, "being found indispensable to all the hypotheses that exclude a deity, she is still preserved in her high office by many of the moderns, and invested with great power, incessant activity, and uncommon prudence. She creates, and brings whatever lives to a state of perfection; and does it all according to method, or agreeably to laws imposed upon her by a higher power, which some call Fate, and others Necessity." We perceive the continual want, which EPICURUS and his followers experienced, in their speculations, of a first cause, one Supreme Being, to whom they might ascribe the various laws by which the world is governed; and we observe the manner in which his place is supplied by properties, powers, or principles, assumed by them to explain phenomena, which, notwithstanding this assumption, must be ultimately referred to one great first cause.

335. LUCRETIUS, the enthusiastic expounder of the doctrines of EPICURUS, after attributing all things to the formative and productive faculties of his atoms, of earth, of the elements, and of Nature herself, thinks, nevertheless, that all must be regulated by diversities of seeds, or of organic particles, each endowed with a peculiar *secreta facultas*, which makes them both living and organic. He is also obliged to conclude that the soul is deduced from a seed — that it is from its seminal qualities, and from this radical difference of its faculties, and not from a difference of organism in the body, that the lion is fierce, the fox crafty, and the stag timid. He rejected the opinion of those who believed that animating principles organised animal bodies; and because he could not see how they did it, he therefore concluded that they did it not. Aware, however, that he might fairly be challenged, in his turn, to explain how his seeds were originally organised, he is quite at a loss, and, forgetting the mechanical properties of his atoms, has recourse to heat, air, and the invisible power of the wind; being, nevertheless, obliged to call in to his aid a certain mobile and active principle, that distributes motion and sensation to them all; but the origin of this principle he cannot explain. The opinions of LUCRETIUS were evidently directed against the vulgar notions of the existence of divinities endowed with moral attributes; but they in no way influence the arguments in proof of a Deity, and a purer system of religion. He admits that it is impossible to disregard the religious feelings and impressions which are interwoven with the very stamina of our constitution; that no nation or individual is entirely without them; that some notions of divine beings are quite irresistible; and that they will spring up in the human mind as things indigenous, without the adventitious aid of education. "Quæ est enim gens, aut quod genus hominum, quod non habeat, sine doctrina, anticipationem quandam Deorum?"

336. *C.* OF MODERN MATERIALISM.—It has been urged by all the favourers of Epicurianism, and by many of the followers of GASSENDI and HOBBES, but more especially by BUFFON, PRIESTLY, DARWIN, MAUPERTUIS, BLUMENBACH, CABANIS, &c., that, as the manifestations of mind are never met with, unless connected with a brain, and are suspended by compression of this organ, so the phenomena generally attributed to it are the result of its organisation. That the combination and reciprocal action of the molecules of matter constituting the nervous fabric, of themselves, and unaided, produce the various powers of mind, is the proposition which they support, however paradoxical it may seem, but which they cannot explain. The possibility of such combinations and reciprocal actions of the molecules of matter producing, unaided, such results, is not shown by any analogy, or by any proof. If mind proceed from certain associations of organic particles, why has not some opinion as to the process been hazarded? Does our experience respecting the mutual influence of either the elements or the aggregate of matter furnish us with resulting phenomena, that can in any degree approach to the lowest manifestations of either vitality or mind? If mind be supposed to be derived only from the combination of these particles, or from the operation of certain of their products upon each other, it may be asked, whether it be possible to conceive that matter, in such a state, possesses qualities of which the elements, or even the individual atoms, are divested? and whether experience has furnished us with any instance of mental, or even of vital, phenomena, proceeding from such combinations, when matter is removed beyond the influence of bodies, or sources already endowed with life? If, on the other hand, properties necessary to the generation of the mental faculties be conceded to every particle entering into the formation of the encephalon, how can the idea of the subdivision of the powers of mind, to such an extent as matter admits of, be allowed? Can the supposition be for a moment entertained, that every molecule of this admirable organ has a fractional part of mind connected with it? Many of the materialists, in order to account for the manifestations of mind, have had recourse to so many suppositions respecting the nature and endowments of matter, in respect either of its elements or of its aggregate, as were tantamount to a negative admission of the principle of vitality against which they had been arguing, — with this notable difference, however, that they required the operation of numerous agents, instead of more

philosophically referring these manifestations to states of this first and noblest constituent of our nature. The genius of Leibnitz saw the difficulty that stood in the way of pure materialism; and, in order to give the atoms of matter activity, and origin to the mental phenomena, he had recourse to the εντελεχειαι, or spirits of Aristotle.

337. Cabanis and the later French physiologists adopted the doctrine of organism; and, in order to supply the want of a foundation to their structure, they seized with avidity upon the opinions of Gassendi respecting the origin of our ideas. Their hypothesis still required support; and, in order that it might receive such from a name looked upon with deference throughout Europe, they unjustly imputed to Locke, opinions which belonged to the two celebrated opponents of Des Cartes already mentioned. Much of the credit which this doctrine acquired in France and in Germany arose also from the neglect with which that class of our ideas derived from reflection was uniformly treated — from the circumstance, that the evidence of the senses and the information derived from experience were considered as the sole foundations of our knowledge. It is very justly remarked by Dr. Barclay, that, if it be supposed that all knowledge is derived from the senses, and that matter is the only object of sense, it must be evident that, on this hypothesis, we cannot with propriety ascribe phenomena to any thing but matter. But on what data is matter, in general, pronounced to be an object of sense? Its ultimate particles certainly are not so; and its aggregates, though many of them certainly are, seem but little calculated to account for life and organisation; and, at any rate, they by no means account for their own formation. But, whatever may be their formation or their consequences, they must be ultimately referred to those primary molecules which are utterly beyond the reach of our senses. Besides, if matter be supposed to include a variety of substances, or rather, every thing that has an existence, it is, on this supposition, no explanation of a phenomenon, to say merely that it proceeds from matter. He who hazards such an assertion, should point out the particular species or the peculiar arrangement from which it proceeds, otherwise he gives us no information, but that it proceeds from something unknown, and which he would wish to be called matter. We may, therefore, safely question the accuracy of the opinion, that all our knowledge is derived from the senses: as well might we say, that arts and manufactures are derived from the doors and windows of the houses by which the raw materials enter, to be afterwards prepared by the industry and skill of the workmen.

338. As our senses are prior in existence to our experience, we have still more reason to question another opinion, brought in support of materialism, namely, that all our knowledge is founded on experience; for a great number of our ideas are not directly derived from our own experience, but rather from the evidence of testimony. Besides, prior to experience, we possess a species of knowledge, which, as to self-preservation, is much more essential than any that we afterwards acquire, which seems to proceed directly from the Author of our being, and which, so far from being the result of our own experience and observation, is the very groundwork on which they are founded. Of this kind is the knowledge immediately derived from those natural instincts and feelings, which regulate the various functions of our system, which stimulate our intellectual powers, and which, according to their strength or their weakness, their healthy or their diseased state, impart a character to our experience, our observations, our reasonings, our conclusions. When we wish but to move a limb, by what experiment or process of reasoning do we come to know the necessary muscles, the particular nerves proper to excite them, or the amount of energy to be imparted to each, so as neither to exceed, nor to fall short of, the object in view? If we take a view of the instincts which guide animals to the selection of food suited to their digestive organs, — to know the appropriate means to overtake, subdue, or ensnare other animals, — to provide against seasons of scarcity, by laying up stores, — to know the distant countries and the different climates where food is in plenty, and to which they can migrate, — to learn that they can sleep during the winter without any food, and to select their retreats so as to avoid discovery, — to calculate the time of sexual intercourse, with reference to the periods of gestation, so that the birth of their offspring may coincide with the seasons suited to their early and future exigencies; — if we consider the age at which most of these phenomena are manifested in the classes of animals to which they severally refer, and the circumstances with which they are generally associated, and if we analyse the entire class of our instinctive desires and feelings (see note, § 66.), as manifested both in man and in the lower animals, we must necessarily infer, that the sources of our knowledge are much more extensive than the supporters of organism would lead us to believe. Let us, therefore, as Dr. Barclay has well enforced, give due importance to these primary causes of action and feeling; for whatever our reasonings or opinions may be, we will find them linked with some one or other of these original springs or energies of our constitution, — with some instinct, appetite, or passion, — with some one of those sources of action, which not only are prior to all our experience, observations, and reasonings; but, what is more, are, during our lives, not infrequently regulated by circumstances, external and internal, over which we have little or no control.

339. If such be the facts, what, then, it may be asked, is the use of experience, observation, and reasoning? The use of these in man is still great — great in proportion to the developement of the intellectual powers. These, and the instincts, can, to a certain extent, mutually aid, oppose, and regulate one another, so as to preserve a juster balance in the moral and social system. The instincts too, as well as the intellectual faculties, may be diseased, may be perverted, or may be deceived, as they have been shown to be in most of the forms of insanity; and in all cases where they point only to immediate objects, or act according to immediate circumstances, they give no warning of the snares, the troubles, and the dangers which are the consequences of indulgence. By following the impulses of instinct, to the neglect of experience and reason, passion and desire lead to acts of moral insanity. As we are able to ensnare, capture, or destroy the lower animals, by taking advantage of their unguarded, unsuspicious

instincts, so we ourselves are often ensnared and captured, or ultimately even destroyed, by excessively indulging many of our instinctive desires and moral emotions, and by neglecting the dictates of experience, just reasoning, and rational observation; or, in other words, from a want of that discipline of which the instinctive and moral feelings are susceptible, and which we have the means of administering, by possessing intellectual and reflective powers in a higher degree of perfection. The control of those feelings, however, is in proportion, not only to the perfection of these powers, but also to the use made of them.

340. I have been thus particular in noticing the opinions of EPICURUS, because they have the same basis, and involve the same principles, as modern materialism; and in showing that the doctrine of GASSENDI and HOBBES, which ascribes all our knowledge to our senses, and which has been seized upon by every writer of note who has more recently written in support of organism, is altogether unsound. — The scope of this work allows me not to pursue further this part of my subject, or to notice the several modifications of materialism which have been proposed in modern, and even in recent, times. This is, however, the less necessary, as what has been already advanced will show the complete insufficiency of any theory based upon organism to account for the phenomena of life and mind.* But I am compelled to examine briefly a modern doctrine which has met with a very favourable reception both in this country and abroad, and which has been applied, by those who favour it, to the study of insanity: — I allude to the doctrine of GALL, or Phrenology, or Cranioscopy.

341. ii. OF PHRENOLOGY. — Of this doctrine, I may observe generally, that some of its principles are founded on opinions which have been, and still are, very generally admitted by physiologists; whilst others, which especially belong to it, are assumptions, which even those who favour it cannot pretend to be proved, or at least expect to be admitted, by sound reasoners, as data sufficiently established. Those who support phrenology, appeal to facts, assert that it is eminently a science of observation and rational induction, and, with apparent candour, call upon those who oppose it, to make themselves acquainted with its principles and details, and then to observe and judge for themselves. This seems rational; but, unfortunately, when the advice is followed, and when the results militate against their theory, they endeavour to rid themselves of the difficulty, by asserting that the observer is mistaken, and unacquainted with the principles of their doctrine, — thus virtually denying that any one can be acquainted with it, unless he be likewise a convert to a belief in it. When, however, pressed by facts which seem irresistible, they have so many ways of eluding the difficulty, and especially by means of their notions respecting the *activity* and *volume* of the individual organs into which they have divided the encephalon, and the developement or activity of controlling, of opposing, and of co-operating organs, that there is at once an end of all argument with them. But the ability and eminence of many of those who have written in support of this doctrine, as well as the reception it has met with, and especially the very intimate relation in which it stands to the pathology and treatment of insanity, require that I should enter upon a more intimate examination of it.

342. That the seat of mind is the brain, is proved by a general consciousness that this is the case, or by a similar testimony to that of the locality of the various senses; and it may be further proved by experiment, — as by dividing any of the nerves, and by observing the resulting phenomena. The same inference is to be deduced from the injuries and diseases to which the brain is liable; by the different grades and forms in which the mind is disturbed, impaired, or its phenomena cease altogether. Whether we can more precisely assign the locality of the mind, or the localities of its different manifestations, than by saying, in general terms, that the seat of mind is the brain, is a question which has been long agitated; and it is upon the affirmation and negation of it, that the believers and unbelievers in phrenology rest their doctrines. It was formerly supposed that the mind was located in the pineal gland; but, as no evidence of this could be adduced, and as it could not possibly be proved by experiment, or supported by observation in disease, the opinion shared the fate of similar hypotheses. That the several faculties and propensities of mind reside in respective portions of the brain, is the fundamental proposition of phrenology. But, as Dr. PRING (*Sketches of Intellectual and Moral Relations*, 8vo. London, 1829, pp. 71.) has well observed, if we seek for the same evidence in support of this proposition, which showed that the brain in general is the seat of mind, no part of it will be found. In our perceptions of the objects of sense, — in the operations of mind, — in the study of music, languages, mathematics, &c., — in the exercise of our passions or propensities, — we have no consciousness of the portion of the brain brought into action; and we cannot thereby assign any of these to one part of this viscus, rather than to another, or distinguish whether the seats of these manifestations or states of mind are different, or the same for all.

343. The proofs of locality afforded by disease or injury are equally inconclusive — or, rather, are not to be found. Extravasations of blood in apoplexy will suspend the mental phenomena, or cause both them and life to cease, in whatever part of the brain they may occur. Whether such extravasation take place in the cortical, or in the fibrous structure, or in any situation; whether fluid is effused from the membranes, or into the cavities; and whether the organic effects of congestion, concussion, fractures, depressions of the cranial bones, inflammations, or softening of portions of the brain, or the developement of tumours, be contemplated, — we find only this common result, that all the phenomena of mind are more or less modified, or suspended; or they cease altogether. They may, however, be almost unaffected by some of these lesions; or some faculties and propensities survive, while others are lost; still the preservation or the loss does not observe any regular connection with the integrity or injury of any given portion of brain. — But to state with more precision and detail the doctrine

---

* For an account of the various hypotheses which have been advanced to account for life and organisation, see the work of Dr. BARCLAY on this subject, and two articles by the author, in the 17th and 18th vols. of the *London Medical Repository*, 1822.

of GALL: — It is asserted — 1st, That the mind presents a certain number of faculties, passions, and propensities, all of which are individually exercised by distinct portions of brain, — which portions are the *organs* of these faculties or passions; — 2d, That these functions are performed, in their respective seats, in different degrees, in the same or in different persons; — 3d, That the strength or perfection of these functions or faculties is in proportion, individually, to the *size* of the organ, and to the *activity* with which it performs its office; — 4th, That these organs are situated in the superficial parts of the brain; — 5th, That in proportion to their size is the protuberance of the skull over them; — 6th, That by an examination of these protuberances, the size of the organs, and consequently the degree of perfection of their respective functions may be estimated; — 7th, That the individual functions may be developed or restrained by education; — 8th, That the preponderance of one or more of them may be repressed by the cultivation of others; — 9th, That the propounder of this doctrine was fortunate enough to discover the great majority of the situations in which the individual manifestations of mind are located, and that the rest have been since ascertained; — and, 10th, That the system is applicable to the prevention and treatment of insanity; mental disorders confirming the truth of it. I proceed to remark briefly on each of those assumptions.

344. *a.* The enumeration of the faculties may or may not be correct. Some of them are not simple, or even original, states of mind, but, as certain of the propensities, arise out of several, which more or less subserve to their individual formation. Then, as respects others, which are considered original and connate, the sphere of action is either too extended or too limited, whilst no attempt is made to trace them to simpler and more original manifestations. The division of the faculties by the phrenologists, moreover, is such, that explanations of character conformably with it, would lead us often to infer, that an individual both has and has not a particular genius, faculty, or endowment, or that he possesses opposite endowments in equal grades of perfection and activity, or that, both being equally developed and active, the balance vacillates between them till some circumstance affects a related faculty, and thus causes it or its opposite to kick the beam. The division of the faculties is opposed to just views of philosophising, and is altogether empirical.

345. *b.* That the faculties and propensities have their seats in particular portions of the brain, which portions are respectively the organs of the faculties and propensities, are two assumptions equally ill-founded with the foregoing. As the faculties of the mind are not distinct entities, but merely states or affections, arising out of impressions on the special or general sensibility, or different modes of consciousness, according as these impressions are internally and externally associated or related, so it is unnecessary to inquire whether these faculties have appropriate or respective seats in the brain. Our experience of what constitutes distinctness of function, in connection with organisation, does not permit us to extend the appropriation of function and organ to the mind and brain any further, than that our consciousness instructs us, that the brain is the seat of mind, or the organ which is most intimately related or associated with its various states and affections; but it by no means informs us, nor even suggests, that these states or affections are the functions respectively of particular parts of the brain, or that these parts are the organs individually destined to perform appropriate offices. Having no proof arising out of our physical and mental constitutions, how then are we to obtain any, or is any conclusive evidence to be obtained? We cannot obtain it either analytically or synthetically, compatibly with the continuance of life. Evidence, therefore, of the loosest kind — analogies, merely, have been advanced, in support of this assumption. As disease or injury has been found to destroy the functions of sense, when implicating either the origins or courses of their nerves, so it has been supposed, from this circumstance, that there are particular localities for the powers of the mind. But this, instead of suggesting the existence of such localities, merely indicates, that the impression from distant parts, or distinct organs, is conveyed by certain nerves, which, when diseased or injured in any part, from their origins to their terminations, are either rendered incapable of transmitting sensation so as to become an object of consciousness, or transmit it in a state of disorder, or imperfectly. Without further pursuing facts which abundantly suggest themselves to every physiologist and pathologist, it may at once be averred, that the proofs in support of the localisation of the faculties of the mind are not merely defective, but altogether wanting, and that the loose analogies which have been advanced, are either inapplicable, or admit of various explanations, none of which come in aid of the proposition.

346. Even admitting that the powers or faculties of the mind exist as separate essences or functions, and that they occupy appropriate seats or spheres of the brain, it by no means follows that these seats are the *organs* which give rise to these powers. The viscera discharging specific offices are denominated organs, because they are the agents, by the instrumentality of which certain results or phenomena take place when actuated by life; and we perceive a very obvious organisation appropriated to the office performed in the liver, kidneys, lungs, heart, &c.; but we are unable to show by what arrangement of the substance of the brain, a mathematical calculation, a process in algebra, a philosophical reflection, a cautious action, or a flight of imagination, is produced. Indeed, the question, whether certain states of mind, which the phrenologists have located in the brain, are really so seated, or should not rather be assigned to different parts of the nervous system, as they have been by most of the ancients, and by many modern physiologists, has not been duly considered by them, but at once have been assumed as *functions* of portions of the brain, which they have also assumed without any sufficient proof as *organs* individually appropriated to the performance of a certain function, and to that only.

347. *c.* It is asserted that the functions are individually exercised in different degrees of activity in the same, or in different persons; but is this owing, when occurring in the same person, to an accidental change in the state of the respective organ? or is the organ under the control of volition? or both? How does volition act upon each of the numerous organs? how is it located so as to bring

each or all into play? and does it run from one to another? or, seated in the pineal gland, or somewhere near, does it reach out certain appliances with which it is provided to each, and thus strike them in every variety of combination? If volition acts upon one, it must necessarily act upon all, or any intermediate number, in every possible mode of combination; and if this were the case, and the volition or desire comprehensive, how immense, both intellectually and morally, would be the result! If it be said that the will can act upon one organ only at a time, how then happens it, that several must often be in operation, to produce the effects which the phrenologists admit as often occurring? That persons may have talents for particular pursuits, or certain propensities, in a greater degree than others, is one of the oldest and best established remarks respecting the human mind. Our experience, however, warrants only the expression, that there is a stronger or a more favourable disposition in some minds, to certain operations, propensities, and passions, than in others. But, as Dr. PRING has observed, that the existence of any one propensity or faculty is independent of all the rest, or requires to be spoken of as more than a disposition of that which is expressed in the gross as the mind, cannot be inferred, — 1st, because the disposition which makes the propensity related with its objects, has the character of a common principle; — 2d, because the objects of a given faculty are presented to it through media — the senses — which are common to all the other faculties; — and, 3d, because one ability is not perfect, or in reality does not exist, without the concurrence, more or less extensive, of others. In truth, there seems little more reason for supposing that the different phenomena of mind are produced by numerous distinct faculties, than that it requires different hands to play different tunes upon a musical instrument.

348. *d.* That the strength of the faculty is in proportion to the size of the organ, is another fundamental proposition of the phrenologists, but an assumption, equally with the preceding, supported only by loose analogy. The only analogical proofs, indeed, which can be adduced in favour of it, are derived from the muscular and nervous systems; and these do not fully apply to the brain: for it cannot be stated with truth, even as a general proposition, that muscular strength, either in man, or in the lower animals, is in the ratio to the bulk of the muscles; nor is it universally true, that the largest nerves convey the greatest degree of nervous energy,—although they generally may be inferred to do this, since they are composed of a greater number of fibrils, each of which, or of the fasciculi into which they are arranged, transmits a certain amount of power, or rather of stimulus, to already inherent power in muscular parts. Moreover, sensibility, which is a principal property of nerves, is not manifestly greater or more acute in a large nerve than in a small one, or in a branch much less than a trunk. The phrenologists are themselves aware of the weakness of this part of their foundation, inasmuch as they have recourse to *activity*, or intensity of action, to explain phenomena which they cannot account for by means of volume. That the size and activity of function of the brain may be connected with the degree of mental manifestation, either singly or conjoined, may or may not be the case. The affirmative has been believed in for ages,—chiefly from the loose analogies already alluded to, and from others presented by various organs or parts. Still, this is the only part of the system which retains any portion of plausibility, upon a strict examination. The alternative, however, of size and activity, is so readily resorted to against the opponents to the doctrine, and so easily suggests itself, as to preclude all argument respecting alleged facts, in proof or disproof of the system, and to betray the mind of the espouser of it into a state of blind belief. It is obvious that, as long as size, relative and absolute, and activity and inactivity in every grade, are made bases of the doctrine, no fact, however faithfully observed, can be adduced, that will shake the faith of those who have embraced it; although every one who will give these articles of their belief due consideration, must come to the conclusion, that they actually negative the propositions they are intended to support: for, if activity of function be admitted as respects certain of the organs into which they have divided the brain, inactivity must be conceded to others, or even to the same organ on different occasions; and, if these states are so important, why have recourse to volume or developement as the principal indication of endowment or function? The shiftings between these states, in argument respecting alleged phrenological facts; the influence of allied or related propensities or faculties on those which are most prominent or most deficient; the countervailing operation of opposing organs; and the different interpretation that may hence be put upon the *ensemble* of these organs as manifested by the cranium,—must render the study, even if tolerably based in truth, as one, at the best, furnishing opportunities of vague guessings into character, in which no two speculators out of many may agree, or arrive at any thing like a just conclusion.*

349. *e.* The localisation of the organs, and consequently of the faculties, in the external or more superficial parts of the brain, whether suggested merely by a desire of detecting their volumes, or by the circumstance of these parts presenting a greater diversity of arrangement, or structure, or form, is immaterial, inasmuch as they both equally fail in supporting the assumption. That the superficial and cineritious portions of the brain are more intimately related with, or instrumental to, the manifestations of mind, may or may not be the case. We have no proof of a conclusive nature, either one way or another; although various circumstances and considerations, not amounting to evidence, have induced several writers to suppose that these parts are actually more especially subservient to the mental powers. Yet, that two or three convolutions, or two and a half, or one and a half, or half or three fourths of one only, should be devoted to one faculty or propensity, whilst the next convolution, or those severally surrounding the portion thus devoted, and even the fractional parts of convolutions not belonging to that portion, should be very differently, or even oppositely, employed, the ultimate arrangement of structure being the same in all, is certainly, if not the extreme flight of imagination, at least the highest

---

* The author, before he was much known as a writer, had his head examined by several of the most eminent phrenologists of the metropolis, but there was no near agreement between any two of them as to his disposition.

pitch of hypothetical conclusion. Numerous other arguments may be adduced against this assumption; but they seem quite superfluous.

350. *f.* That the protuberance of the cranium marks, and is proportionate to, the developement or size of the particular organ of the brain underneath, often obtains, but not universally, or even generally. But this concession in no way supports the general doctrine, — even although the protuberance of the cranium truly and constantly expressed the volume, or rather prominence, of the part of the brain underneath. However, this correspondence very often does not exist, even in early life, for reasons that will suggest themselves to every anatomist. We find, moreover, and not infrequently, that there are prominences in the cranium, where there are underneath no corresponding developement of brain; and that the skull is impressed internally by irregular enlargements of the convolutions of the brain, and yet no external projection can be observed, corresponding with the concavities in the internal surface. But the phrenologists contend, as we have seen, that the size of an organ is in proportion to the strength of the faculty; and further, that a faculty, not naturally very strong, may be greatly strengthened by education or habitual exercise, even at advanced periods of life. Now, it may be asked, Is it to be expected that, at adult or advanced age, as the faculty gained strength, and as the organ, as they suppose, becomes increased in volume, the portion of cranium placed over it, will be protruded before it, so as to indicate the amount of increase? None but phrenologists could even dream of such a change as this in the skull at these periods of life. Here, however, they may shelter themselves behind activity, instead of bulk, or, if they still stick to the latter, and it evidently appearing that the bone does not yield to the growth of the subjacent organ, either the organ itself, or those around it, must be damaged by the consequent pressure — those in the vicinity must be atrophied, in proportion to the hypertrophy of the exercised part, and their functions injured accordingly, or even altogether annihilated.

351. *g.* It is evident, that the proposition directly based on the foregoing, — namely, that the strength of the faculties may be estimated by an examination of the projections and depressions of the skull, — requires no further remark. That faculties and propensities may be developed or restrained by education, is, and has long been, admitted, within certain limits. That the faculties acquire facility of action from exercise, provided that the exercise be neither excessive nor too long protracted, has been generally allowed. The passions and propensities also acquire strength from indulgence: but this is not regularly or universally the case; for, as remarked by Dr. Pring, a passion, which, in the earlier periods of its gratification, was vehement, might give place, after continued indulgence, to an apathy with respect to the same objects; and, in other instances, the excessive indulgence of almost any passion or propensity may terminate in disorder of it, or even in its imbecility, or total extinction. That the predominance of one passion or faculty may be restrained by the cultivation of another, is an old observation, which is not so universally correct as generally supposed, but which is received as an established axiom by the phrenologists, as it agrees with the belief in the distinctness of the individual mental functions, and of their respective organs. As respects the passions, we generally observe, that when certain feelings are frequently called into action, those which repress them, or are incompatible with them, are inactive, and less disposed to manifest themselves. This, however, does not extend to the purely intellectual powers; for, as regards them, we do not find that the cultivation of one power enfeebles the others; it merely tends to the formation of opinions unfavourable to the employment of another power. All that our existing knowledge permits us to advance on this topic is, *that certain modes or states of conscious sensibility or mind, being called into existence and action by their respectively related internal or external causes or occasions, these states continue to manifest themselves with an activity, generally corresponding with the intensity, character, repetition, and duration of these causes; and that a disposition thus to manifest themselves exists in proportion as they have been called into action, or thus exercised; other states of mind becoming inactive from the absence or insufficiency of those causes or occasions which are especially related to them, but assuming activity whenever these causes come into operation.*

352. This proposition is equally applicable to the intellectual faculties, and to the propensities or passions — to imagination, and comparison, and reasoning — to the benevolent and to the malevolent emotions; and is aptly illustrated by Dr. Pring, who remarks, that a disposition to cruelty may be repressed for many years, by a cultivation of the sentiments of benevolence, &c.: these sentiments may prevail until the age of thirty, when, from injurious treatment, or unfavourable observations of human nature, it may be suggested, that mankind are altogether unworthy objects; that they merit hatred rather than love; that, instead of the kinder offices, no species of cruelty is too bad for them. The original propensity would then be resumed, perhaps, even in greater force, from the contrasted sentiments which had been previously entertained, or from having been so long repressed.

353. *h.* It is obvious that, before the seats or organs of the faculties and propensities can be respectively assigned in the brain, it must be shown — *first*, that these faculties are severally distinct; and, *secondly*, that each occupies an appropriate and equally distinct portion of the brain. These propositions, however, have been already examined, and rejected for want of proof. Notwithstanding this, the phrenologists assert, that those persons who have certain faculties and propensities in a high degree, have certain protuberances on the skull, by which these faculties are denoted, — these protuberances being the external signs of the cerebral organs, and of their respective offices; and they support this assertion by the formation of the crania of those who had certain faculties and propensities in an unusual degree — these crania, as they aver, all having a protuberance for the same faculty in the same part or situation. But this practical application of their doctrine, upon the truth of which its utility entirely depends, altogether rests upon the facts which have been adduced in support of the proposition that the same faculties are always indicated by the same external signs, in respect of situation and developement. The number and correspondence of the facts, however, are denied by those who do not believe in

phrenology. It is obvious to those who think, that all physiognomical systems — that all attempts to establish a doctrine, by which the character shall be known from the external appearances of even a part, or of the body generally—may be supported, however *bizarre*, by a certain number of coincidences, which may be viewed as facts proving its truth. When we take into account the number of the mental affections and faculties, the diversity of intellectual and moral character, and the endless varieties of form of the head, face, and body, and of their expressions, it must be obvious, that any theory in which there is a reference of faculty to form, will necessarily find support in a large number of coincidences, — it cannot possibly be otherwise; and, if these coincidences be assiduously sought after, recorded, and marshalled as proofs of its truth, to the neglect of facts which disprove the connection attempted to be established, the theory will appear to many, and especially to those who are seldom at the trouble to think for themselves, a most brilliant discovery, — and the more so, that it promises an almost intuitive knowledge of character, and the most useful practical application. It is not denied, that some skulls present, in connection, — but, as far as the thing is yet proved, only in coincident connection,—certain propensities and faculties with certain external signs; nevertheless, it is confidently averred, that others evince no such correspondence between the mental character and the external form, and even contradict it in all, or in the most remarkable, of their respective parts. In the alternative, however, of activity, the cranioscopists have a refuge from adverse facts — and, as I have already hinted, from sound argument; and behind this, and various circumstances, — as controlling, deficient, inactive, and concurring organs, — they endeavour to intrench themselves. There are numerous other circumstances and considerations which strongly militate against the doctrine of GALL; but the scope of this work will not permit me to adduce them. The reader will find this topic more fully treated of in the able work of Dr. PRING already referred to.

354. *i.* The applications of cranioscopy to the pathology and treatment of mental derangement that have been made by those who believe in it, cannot be entertained; for, as it appears, from the reasons assigned above, and from others that might be adduced, not to be based in truth, such applications of it can only mislead, or interfere with juster views, or even be productive of irreparable mischief.

355. Having thus disposed of a doctrine which has received very considerable support, and which has been viewed by those who entertain it, as being of the greatest utility in understanding and managing mental disorders; although, even if most firmly based in truth, the utility of it in this respect is neither so great nor so obvious as they would wish it to appear; it further remains, briefly to consider the probable nature of the connection of the mind with the brain and nervous system.

356. iii. OF THE CONNECTION OF THE MIND AND NERVOUS SYSTEM.—*A.* Those who have reasoned against the possibility of the existence of the mind separately from the body, have referred to the general agreement of the state of the former with that of the latter, and to the effects produced in the manifestations of mind by disease and injuries of the brain, as proofs of the truth of their doctrine. But the inferences drawn from these two classes of facts, as Dr. PRING justly observes, are by no means legitimate. As to the first class of facts, showing a correspondence of vigour, at different periods of life, between the mental powers and the corporeal functions, it may be remarked, that the changes in these severally, although to some extent simultaneous, are not so universally, nor always in corresponding degrees: the faculties of the mind are sometimes unimpaired at far advanced periods of life, and the brain is fully developed long before the mental powers are in full vigour. Admitting, even, that the progress of the mind from infancy to old age is in general agreement with corporeal developement and strength, yet it does not *on this account* follow, that the changes of the mind, in the course of age, are *dependent* upon those of organisation. There may be a simultaneous developement without a necessary dependence. Besides, if the mental powers are entirely owing to the brain, — are merely functions of this organ, — wherefore are they not displayed at an equally early period of life with those of the liver, stomach, and other organs, — all of which manifest a perfection of function, either soon after birth, or, at least, long before the mental powers are fully developed? According to the doctrine of organism, no answer to this question can be given; whilst those who believe that, in the present state of our knowledge, it appears impossible for matter to give rise, of itself, to life or mind, and that a principle of vitality is necessary to the attraction of material or inorganised molecules into specific organised forms, and to be allied and associated with them for the purpose of enabling them to discharge appropriate functions, will readily respond, that in the early part of their existence, the brain and nervous system are the instruments chiefly, under the dominion of life and mind, of sensation, and of the instinctive feelings and emotions; and that, as fast as the mind is stored with the reports of the senses, — as fast as conscious sensibility is called into action, so as to form perceptions, and to perfect the results of sensation, — so it becomes also capable of retaining and comparing the objects of its consciousness, of reasoning and reflecting upon them, of suggesting new forms or combinations of them, and of drawing inferences from various sentiments or feelings arising out of the internal and external causes or occasions which influence or excite it.

357. The class of facts, consisting of modifications or suspensions of the mental powers, from organic lesions, and injuries of the brain, has been considered, by the supporters of organism, as conclusive proofs that the mind is a function merely of this organ, that can exist no longer when the fabric of it is destroyed. But it by no means follows, that, because those powers are destroyed by disease of the brain, they are, therefore, the product of the organisation of this organ. All we know is, that a certain degree of soundness of the latter is usually necessary to mental sanity; and that the mind shall be, in one case, severely disturbed by a slight change of structure; in a second case, but slightly disordered by most extensive disorganisation; in a third, unaffected by very remarkable lesions; and, in a fourth, most violently affected, without any appreciable alteration. Here, although the facts contended for are numerous, yet they neither correspond with one another, nor do

the lesions produce corresponding or co-ordinate effects on the mind; nor are the modifications of mind always to be referred to morbid conditions of the brain, — the results are neither uniform, nor correspondent, nor universal, — and hence the intimate dependence of mind upon the brain is not a legitimate inference from this class of assumed facts. The dependence of one thing upon another, it should be recollected, may be of different kinds: — 1st, It may be that of absolute cause and effect, — the latter existing only in consequence of the former, and ceasing with it; — 2d, The dependence may be one of association or connection, — in which state the one cannot be manifested without the other, and any disturbance of either will have a reciprocative influence. The dependence may be either of the foregoing kinds, and be greatly affected by the contingent interference of a third, or foreign influence, not requisite to the existence of either, and especially of that which suffers a change from such interference. Whilst it is the first of these that is contended for by many, the second appears to be the kind of dependence that naturally subsists between the mind and the brain; the contingent interference of morbid action in the brain disturbing the states of the mind, and the structural conditions of the brain itself.

358. The exercise of the faculties of the mind is dependent upon a cause which is allied with, or which actuates, the brain, and is modified or suspended in consequence of disease or injury of the brain, not because the integrity of this organ *produced* these faculties, but because the exercise of them is prevented by the foreign influence of a preternatural state of the organ with which they are allied. On this topic, Dr. Pring justly remarks, that in the case of disease or injury of the brain, followed by suspension of the functions of the mind, we do not know the agents or the mode by which such suspension is produced. We perceive a change in the condition of the structure; but whether the action of the mind ceases, because a material arrangement is disturbed, upon the precise state of which the action of the mind depended, as upon an essential cause; or whether this action ceases, because it is impeded by the foreign or preternatural influence of a fabric with which it is allied; we are precluded the discrimination of experience. Yet the alternatives have this important difference, — that, in the former case, the mind cannot exist without a precise arrangement of a material structure; in the latter, it may exist independently of such organisation; and, although liable to be disturbed or suspended by change of organisation, in the same manner as any other effect may cease under a foreign influence, yet its exercise may be resumed, when this influence is withdrawn.

359. The dependence of the mind upon the ganisation of the brain is said to be most unequivocally shown by the effects of *compression* of the organ; but compression, like organic lesions, may impair or suspend the manifestations of mind, whether they are a result of a certain state of organisation, or whether they are only allied or associated with it. In the former case, the effect is one of necessary dependence upon its cause, — the function ceasing upon a certain preternatural condition of the organ; in the latter, the foreign interference disturbs or suspends the condition of the material fabric with which mind is associated, and as soon as this interference and its material consequences are removed, the manifestations of mind are restored more or less completely, according as the removal of the foreign cause of disturbance is complete.

360. It follows, from what has been advanced above, that disorder or suspension of the manifestations of mind, from disease or injury of the brain, is no proof that the mind is necessarily a *function*, or an effect or product of this organ; but merely that the brain is the organ, instrument, or medium of communication between the mind and the external world.

361. In favour of the belief that the mind is independent of the material fabric with which it is intimately allied or associated, or is a result of vital properties superadded to, and actuating, this fabric, numerous considerations and satisfactory evidence, if my limits could permit, might be adduced; but it may be remarked, — 1st, That the circumstance of the opposite doctrine, or that of organism, having been found fallacious and untenable, the only other doctrine, by means of which the phenomena of mind and organisation can be explained, appears the more entitled to credit; — 2d, That mind ceases to be manifested in consequence of an organic lesion in a particular or limited part of the brain: if the mind were the result of the organisation, there is no reason why it should not still be produced, wherever the organisation is perfect; — 3d, That the principle or properties of life, endowing living animals from conception to death, and the structures which life endows and actuates, are undergoing a perpetual change, and, as existence advances, a perpetual consumption, without any loss of identity; that both the original vital endowment, and its associated structures, are perpetuated from inorganic or from broken down vegetable or animal substances, as from their elementary sources, — these substances containing the constituent properties or elements of life and of structure; that this conversion and appropriation of the elements of life and structure are performed by the changes produced in, and by the affinity or attraction exerted on, these elements contained in dead or inorganic substances, by life; and that this attraction is one of assimilation, by which a living principle separates, adopts and unites its own properties or elements, and those of its allied structures, from the various materials furnishing them, thereby perpetuating their forms, as long as their own identity or existence is preserved, and as long as their elements are submitted to the influence, or brought within the sphere, of the vital endowment, or principle, which alone is capable of thus acting; — 4th, That it is observed of *functions* generally, that they are the results of life in conjunction with structure — of organisation built up and actuated by the vital principle endowing it; that the function of every organ is dependent upon the continuance of its life; that it is not produced by the organisation, — for the material elements composing the individual tissues and the general organisation are held together in a state of affinity or attraction and cohesion opposed to that which their chemical affinities dispose them to assume; that this predominant affinity and cohesion are owing to a vital endowment, and are therefore aptly denominated vital; and

that, whilst it thus holds the material elements in a due state of attraction, appropriately to the constitution of the several tissues, it also enables them to discharge specific or peculiar offices or functions; — 5th, That, this dependence of function upon vitality existing throughout the body, a similar dependence of function upon vital endowment may reasonably be extended to the brain; — and, 6th, That the evidence we possess as to life being the cause of the organisation of material elements, and of its own perpetuation or renewal, as well as that of its allied structures; and as to its being a principle superadded to, intimately allied with, and actuating, a material fabric, and of which evidence such notice as the scope of this work will permit has been taken above (§ 336. *et seq.*), and in the article DISEASE (§ 2. *et seq.*), is sufficient to show, that the mind is the result of the vital endowment of the brain, without which endowment this organ would not only cease to be the instrument of mental manifestation, but would also fall into dissolution; its material elements, no longer being held together by the attraction of life, assuming those forms to which they are chemically disposed. According to this view, the evidence in favour of the immateriality of mind is the same as that upon which the doctrine of vitality, or the primary agency and controlling influence of life upon structural arrangement or organisation, and upon function, is based; and mind thus appears the highest manifestation or property of life, in connection with, and through the instrumentality of, the brain — that particular congeries of tissues, in alliance with which only could its wonderful faculties become apparent.

362. Matter is known to us only by our senses; mind, by our consciousness. We know quite as little about the essence and occult qualities of mind, as we know of matter; and, as far as our most profound conceptions of them can carry us, we have no ground for believing that they have any thing in common, beyond their derivation from parents, and the support or renovation they derive from surrounding media and materials furnishing the properties and elements of their developement, perfection, and perpetuation. The principle which thinks, as Dr. ABERCROMBIE remarks, is known to us only by thinking; and the substances which are solid and extended, are known to us only by their solidity and extension. When we say of the former, that it is immaterial, we simply express the fact, that it is known to us by properties altogether distinct from the properties to which we have given the name of matter, and, with the exceptions just adduced, has nothing in common with them. Beyond these properties, we know as little about matter as we do about mind; so that materialism is hardly less extravagant than would be the attempt to explain any phenomenon, by referring it to some other altogether distinct and dissimilar, — to say, for example, that colour is a modification of sound; or gravity a species of fermentation.

363. We have, in truth, the same kind of evidence for the existence of mind, that we have for the existence of matter, — namely, that furnished by its properties; and of the two, the former appears to be the least liable to deception. Of all the truths we know, says Mr. STEWART, the existence of mind is the most certain. Even the system of BERKELEY, concerning the non-existence of matter, is far more conceivable than that nothing but matter exists in the universe. To what function of matter can that principle be likened, by which we love and fear, are excited by enthusiasm, elevated by hope, or sunk in despair? These and other mental changes may be equally independent of impressions from without, and of the condition of the bodily frame. In the most quiet state of every corporeal function, passion, remorse, or anguish may rage within; and while the body is racked by the most distressing maladies, the mind may repose in tranquillity. The mind thus being so frequently uninfluenced by the state of the bodily organs, and so dissimilar and distinct from the functions of these organs, what reason have we to believe that it is dependent upon organisation, further than in being intimately allied with it, for the purposes of intercourse with the external world. When these purposes are fulfilled, this alliance is divorced; and as *mind*, the highest grade of vital endowment, is insusceptible of decay, although liable to be variously disturbed by diseases of its allied fabric, the connection ceases generally, in consequence of the state of this fabric having become incompatible with its manifestation. As soon as the *organic life*, or lower grade of vital endowment, or the properties of life actuating the organs of digestion, assimilation, circulation, respiration, and nutrition, and giving rise to functions subservient to the display of mind, by means of the brain and nervous system, cease to be exerted on their respective organs, the vital cohesion of all the structures ceases, and changes take place in the arrangement of their constituent elements. These structures, however, are not annihilated, their elements have only changed their forms; thereby furnishing an analogical proof, as remarked by Dr. BROWN, of the continued existence of the mind or thinking principle, — that it survives the disorganisation and changes experienced by its allied fabric, by means of which its properties or powers are displayed, and the various relations subsisting between it and the rest of the creation are established and preserved.

364. *B.* If we endeavour to inquire into *the origin of mind*, all the information which our faculties enable us to obtain, amounts merely to the following; — that, in common with the other properties of life of which the structures are possessed, it is derived from parents; is developed by the changes in the constituents of the ovum; is matured by the processes of growth; is allied with an appropriate organisation, or material fabric; and, like the other vital properties, subsequently manifests the phenomena which result from its own nature, and the agency of related causes. It is alone sufficient to establish, as Dr. PRING well remarks, the derivation of the mind from parents; that the being who exhibits the possession of it, is a production from parents; that he is so endowed by an internal conformation, the materials of which are obviously from parental sources; and that he is not cotemporary with parents, but is a production peculiar to a more or less advanced and perfect period of their existence. The peculiar features also of the mind of the offspring are often found to resemble conspicuous ones which belonged to the parents; or, like the hereditary peculiarities remarked in the structures, the mental characteristics of parents are not manifested in the succeeding generation, but remain latent, and

are displayed by the one which follows. Thus, insanity is as conspicuously transmitted from the parents to the offspring, as any one of the hereditary corporeal diseases. The association, however much or little, with the good or with the bad, with the well-informed or with the vulgar; the being familiarised with scenes or sentiments which captivate the imagination, or with topics which exercise the reason; or confinement to a sphere in which the mental impressions and exercises are little more varied than those of a horse in a mill, — will individually have an effect upon the character of the mind, and will concur, with previous relations of growth, to disguise its resemblance to the original from whence it proceeded.

365. From these and various other considerations, it may be inferred, that the embryo derives its vital properties from both parents, — those of either parent somewhat predominating in certain cases, and as respects certain properties; that these properties vary in grade, in different classes of animals, the highest of which furnish incontestible proofs of the possession of several of those faculties which we attribute to mind; and that the same grade of vital properties is communicated to the embryo as characterise the parents,—these properties developing, in the embryo, the material fabrics, or structural arrangements, about to become the instruments or media of their manifestation; mind, and especially the powers of association and reflection, being the highest grades of these properties, and requiring a more complete developement of the brain for their display.

366. C. If then the conclusion, that the mind is not a mere result of structural arrangement, is deducible from satisfactory evidence, it remains to inquire still further, *for the relation subsisting between the mind and the material fabric with which it is associated.* A perfect account of this relation is most probably beyond the reach of our faculties; but amongst various other topics it comprises much of what has already been alluded to, as well as a statement — 1st, of the circumstances upon which the existence of a mind or intellectual principle depends; 2dly, of the mode of its connection with the material fabric; — and, 3dly, of the mode by which changes or conditions of the mind, and of the organisation, affect each other: but to these topics I can only briefly and imperfectly allude.

367. *a.* Most of the circumstances upon which the existence of mind depends have been noticed, as far as they are known to us. It has been shown above that the powers of mind are the highest properties of life evinced through the medium of a perfect nervous system; that these powers, with the other properties of life, are derived from parents; that they are developed during the early stages of existence; that they become known to us only through the instrumentality or medium of a cerebro-spinal nervous system, actuated by the vital endowment of the frame; that the phenomena of mind are produced chiefly by relations subsisting between it and external objects, — by sensations transmitted to the brain and there disposed of, according to their relations with the other properties or powers constituting the intellectual principle or mind, and partly also by its powers of suggestion, abstraction, comparison, and reflection; and that the connection of mind with its material fabric is one of alliance, and not of necessary dependence, or of dependence only as far as the structure may be required as a medium between the mind and external objects, or may concur to its support or phenomena.

368. *b.* The *bond* or *connection* subsisting between mind and organisation can be viewed only as one of affinity or *alliance;* and the sole reason we can assign for this connection is, that it is a law of nature. We have seen, that this alliance is of such a kind as that the *existence* of mind is not necessarily dependent upon the material fabric; but that we are rather entitled to consider the organisation to be dependent upon life, mind being those manifestations of life evinced by the cerebro-spinal nervous structures, and resulting from the vital endowment actuating these structures; for it is impossible to conceive that an organised body could have come into existence without a vital or animating principle; and it is equally impossible to conceive how an animating principle, and more especially its higher properties or powers, — the faculties of mind, — could have been manifested or duly exerted, unless in most intimate alliance with matter, the molecules of which it could so build up and actuate as to render them the media and instruments of communication with the other materials constituting the visible world. When, however, the molecules of matter are thus built up, variously formed, and actuated, they are incapable of perpetuation, in their numerous and wonderful states, or even of more than a momentary existence, unless in alliance with, and endowed by, life — by that life which organised the molecules of matter, developing and perfecting them in their respective forms and grades of being. As soon as the alliance of life and organisation is divorced, the former escapes the cognisance of our senses, our unaided reason being incapable of acquainting us with its subsequent states of alliance or existence, and the latter returns to its elementary states. Thus we perceive, that organisation, with all its phenomena, is dependent upon life from its commencement to its termination, — its commencement resulting from the vital endowment bestowed at first by parents, and perpetuated afterwards by assimilation; its termination, ultimately, being consequent upon the loss or departure of this endowment, without which it can no longer exist. But, whilst organisation, with all its functions, is the result of, and is necessarily dependent upon, a vital endowment, in all its grades and manifestations, this endowment is not necessarily dependent upon organization, although associated with it in such a manner as fully and duly to actuate it; and this latter conclusion is supported by the reasons assigned above (§ 356.), as well as by the consideration that life, in all its grades, may exist independently of the material fabric which it actuates, although placed beyond the spheres of our senses. This is not above the range of conception or of probable existence, but admits of belief equally with other remote causes of visible phenomena; whereas the dependence of life and of its highest manifestations, or mind, upon organisation is incompatible with our experience of the numerous objects composing the external world, with our conceptions of possible phenomena, and with their causation, perpetuation, and termination.

369. *c.* The *mode* in which changes of the mind and of the organisation affect each other

can be only obscurely or imperfectly recognised; but, still, enough is manifested, to show—1st, That changes in the manifestation of the mind affect the organisation by primarily disturbing the functions of life in organs intimately related to the nervous system;—and, 2dly, That changes in the organisation affect the mind, in consequence either of the molecular arrangement of the material fabric, necessary to the healthy state of mind, being disturbed, or of the affinity or alliance existing between this fabric and its vital endowment being weakened or deranged, or of disorder of this endowment occasioned by the changes of its associated material fabric,—these changes deranging the manifestations of life usually evinced by the brain. Each of these propositions require further remarks.

370. 1st. In illustration of the influence of the mind upon the organisation, it may be stated that the depressing passions impair the functions of digestion, and weaken the action of the heart; and, if these effects are intense or prolonged, the organisation not only of the digestive and circulating viscera, but also of the brain, becomes affected through the medium of the nervous and circulating system. Here we perceive that changes in the functions of an organ affect both that organ itself, and also other organs related to it, by means of nervous and vascular connections.

371. 2d. If the structure of the brain be changed, the consequences are not uniform, either as to extent or character: there may result disorder—1st, of the mind; or, 2dly, of connected or related functions; or, 3dly, of both mind and related functions. Yet these consequences are not necessary or absolute, they are merely contingent—they are not constant or uniform, but uncertain and frequent: for numerous facts prove that the fabric of the brain may be most palpably and variously changed, without the mind being appreciably disordered; and that the most severe mental disturbance may suddenly occur, and as suddenly disappear, where no lesion of the organisation of the brain can be detected, or even inferred. These facts lead to the conclusions—1st, That changes in the mind, or vital manifestations of the brain, do not result uniformly, or even generally, from a disturbance of the molecular arrangement of this organ;—and, 2dly, That changes in the mind depend either upon impairment or other derangement of the affinity or alliance subsisting between the fabric of this organ and its vital endowment, or upon alterations in the state of this endowment, whether occasioned by lesions of its associated structures, or occurring independently of such lesions. To either, or both, of these alterations, disordered states of mind may be imputed; and either of them will explain the fact that these states of disorder proceed in some cases from alterations of structure, and in others without any appreciable alteration. They both—especially the latter—explain those sympathetic states of mental disorder which are of so frequent occurrence. Thus, the organisation, or even the function, of a remote organ is seriously disturbed, and the vital manifestations of the brain, or the mental powers, suddenly become more or less disordered, and as suddenly are restored to their healthy state. There is, however, no reason to conclude, that the material fabric of the brain is altered in such cases. All that we are entitled to infer is, that the change in the primarily affected organ has so disturbed the vital endowment of the frame, as to disorder in a special manner the manifestations of this endowment in the brain and nervous system; or, in other words, so as to derange the states of mind, or the various conditions of conscious sensibility, in relation to its internal and external causes.—From the preceding observations, and from numerous facts and considerations which my limits would not admit of being adduced, I may state the following inferences, as possessing more or less of practical importance, especially with reference to mental disorders; although their practical bearings may not be very obvious to the empirical or routine practitioner.

372. (1.) An organised being did not organise itself; the creature did not create itself, but was created; and all we know with precision, especially in respect of the origin of the more perfect animals, is, that they have proceeded from parents or anterior living existences.

373. (2.) Our present knowledge warrants the conclusion, that the derivation of organised bodies from parents depends upon certain material elements which proceed from both parents, and which are endowed, or associated, with a vital emanation from these parents,—the combination or mutual influence of these elements and of their vital endowment producing the new animal; and that the material elements furnished by the parents toward the production of their offspring, and vitally endowed by them, are of such a nature as to admit of conversion, under the influence of life, into those tissues more immediately required in the early stages of developement, and of separate existence, of the offspring.

374. (3.) Every consideration of the subject confirms this inference,—that not only does a vital emanation proceed from each of the parents, in connection with the material elements furnished by them towards the formation of the new animal; but also, that this emanation, or vital endowment, is possessed of properties, although in a latent or non-manifested state, similar to those possessed by the parent which furnished it; and that the vital emanations or endowments proceeding from parental sources, combine in producing the new animal, and form and develope the material elements with which they are allied or associated.

375. (4.) There is every reason to infer, that the embryo derived from these sources requires to be furnished, for a time, with those elements of assimilation necessary to its developement, and to its future state of independent existence; and that such assimilation and developement are accomplished by means of the vital endowments derived by both parents, although reinforced or promoted, or at least favoured, by the circumstances in which the embryo is placed in respect of one of its parents.

376. (5.) The animal, being thus organised by means of vital endowments derived from these sources, is afterwards supported by these endowments; the offices performed by each and every part of its frame, whether tending to the continuance of its existence, to the perpetuation of its species, or to communication with objects external to, and remote from, it, depending upon these endowments being weakened as they become impaired, or disordered as they are disordered, and ultimately ceasing immediately when they disappear or depart from the body which they thus preserved and actuated.

377. (6.) An organised body thus vitally endowed, presents an assemblage of organs, each of which performs, whilst actuated by life, certain offices or functions; their tendency or purposes being—1st, to continue the existence of the animal, by assimilation of the elements of matter external to itself; — 2dly, to perpetuate the species; — and, 3dly, to hold relations, more or less extensive, with the physical, and, in man, also with the moral or social, world. These organs or viscera are respectively endowed with life, which is either intimately associated with a general system or tissue, supplying all organs and parts of the frame, or is more generally diffused to all the structures, and even partially also to the circulating fluids; and they manifest this endowment in various modes, according to their organisation; their offices or functions being performed under the influence of life, and only by means of its influence, but through the instrumentality of the organisation. The functions of a living animal being thus altogether or entirely dependent upon life, these functions may be viewed as the manifestations or properties of life through the intervention or medium of the structures. Thus, irritability is a manifestation or property of life by means of the muscular system, and the various modes of sensibility are manifestations or properties of it evinced by a cerebro-spinal nervous system.

378. (7.) Conscious sensibility, in all its forms, and the intellectual and moral states, in all their varieties, arising from the relations of consciousness with its numerous external and internal occasions, are the highest properties or manifestations of life through the instrumentality of the brain—perfected, however, or called into existence or activity, by sensation, education, and reflection. These manifestations of vital endowment by means of a perfect nervous system, are the properties, powers, or faculties of mind, which are known to us only in alliance with this system.

379. (8.) The powers of mind, being, then, the highest properties and manifestations of life, through the medium of a perfect nervous system, are dependent upon the vital endowment of the frame, or result from this endowment whilst actuating its allied material fabric; the states of conscious sensibility, or of the mental principle, depending as much upon it as upon changes in the organisation of the brain itself. The faculties of mind are, therefore, manifestations of the vital endowment, through the instrumentality and medium of the encephalon: this endowment, in actuating this particular part of the fabric of the body, evincing these faculties, or mental phenomena. In this process, it is obvious that the particular conditions of the general vitality, whether as to power, or character, or quality, must influence the results, or the manifestations of mind, independently of any change, of an obvious or appreciable nature, in the fabric of the brain; and that disorders of mental manifestation will proceed as much from the conditions of the general vital endowment, as from alterations of the structure of the organ.

380. (9.) It having been shown above, that the vitality of the frame, as it endows and actuates the brain, is not necessarily dependent upon, but is merely allied or associated with, the brain, it follows, that changes of the structure of this organ may or may not affect the mental powers, so long as they are not of such a nature as to seriously disorder the vitality of the frame; and that, when the mental faculties are deranged in consequence of alterations in the fabric of the brain, the disorder is owing to the disturbance which such alterations produce in either the general or the local vital endowment, or both; the local lesion affecting either the general vitality, or that part of it endowing the encephalon more particularly, or both, contingently and frequently, but not necessarily or uniformly.

381. (10.) The alliance of the vital endowment with the material fabric being intimate, it may be inferred that affections of the one will disorder and ultimately change the other, when intense or prolonged—although in persons possessed of robust frames, and much vital energy, the disorder of either may be severe, without its associate being seriously changed. Intense affections of mind hence may, or may not, change the allied fabric, and *vice versâ*, according to the susceptibility of the system, and various other concurrent circumstances. This being the case, much of the structural lesion observed in old cases of mental disease, is as probably the result, as the cause, of such disease; the prolonged disorder of the vital endowment of the brain ultimately modifying the organisation of that structure or fabric which was the instrument or medium of the disordered manifestation. In such cases the mental affection will influence the general as well as the local vital endowment, although it is primarily merely a disordered state of that endowment, either generally or locally, and react upon it to such an extent as ultimately to change the allied fabric either of the brain or of remote organs.

382. (11.) As the powers of mind are manifested only through the medium of the encephalon, and are not the products of its organisation, — as they are the higher properties or manifestations of life only in alliance with, and through the instrumentality of, this organ, — and as affections of the vital endowment, or disorders of these manifestations, and changes of the intimate fabric of the encephalon, only contingently and frequently, but not necessarily or generally, disorder each other, — so it follows, that the amount of the disorder evinced by the mental power is no index to the extent or nature of the change existing in the brain, nor even a proof of the existence of any such change; and further, that the extent of change in the encephalon produces no correlative disorder of the mental powers; and that most extensive lesion may be present in the former, without the latter being materially, or even at all, disordered.

383. (12.) Although lesions of the brain are often evinced by disorder of the mental powers, they are more generally and certainly indicated by the physical disorder, or by phenomena displayed by distant, but related, parts. When lesions of the brain exist in connection with disorders of the mind, these lesions in respect both of their nature and extent, are indicated rather by the physical than by the mental phenomena; the states of the general vital power, or endowment, being kept in view.

384. (13.) Disorder of the vital manifestations of the brain being as dependent upon the states of the general and local vital endowment, as upon alterations of the fabric of the encephalon, or even more so, it follows, that the states of this endow-

ment, generally and locally, and in connection with changes of structure in various or remote, but related, parts, should form the bases of our pathology of mental disorders, as much as lesions of the fabric of the encephalon; and ought, moreover, to be the grounds and guides, as much as they, of our therapeutical indications, and the guides of our intentions and means of cure, whether hygeienic, moral, or strictly medical.

385. VIII. TREATMENT OF INSANITY.—There are few maladies which are more successfully treated than insanity, when the means of cure are promptly employed, and appropriately to the varying forms and features of individual cases; and there is none which requires, in order that all possible success should be obtained, a more comprehensive knowledge of morbid actions, of the disorders not only of the brain but also of the other viscera, and of the intellectual and moral manifestations, as variously modified, influenced, or disordered, by the predominant feelings, the manners, the prejudices, the dissipations, and the vices of society. In attempting to give a full exposition of the treatment of mental disorders, as far as the existing state of our knowledge will enable me, it will be necessary — *first*, to offer some observations generally applicable to the treatment of insanity; — *secondly*, to state the means which seem most appropriate to the different forms of the malady; — *thirdly*, to estimate the value of the principal remedies, in the several states of derangement;—and, *fourthly*, to consider the moral management of the insane.

386. i. REMARKS MORE GENERALLY APPLICABLE IN THE TREATMENT OF INSANITY. — It was formerly too much the practice to treat the insane according to a certain routine or system, without reference either to the causes, or to the form, of the malady; and the routine or system followed was generally based upon some prevalent doctrine applied to it, or some generally adopted system of pathology. Thus, the Ancients had recourse to drastic purgatives, and especially to hellebore; the discovery of the circulation of the blood led to the employment of sanguineous depletions; and the general adoption of the humoral pathology, at a still more recent period, was followed by a revival of the use of purgatives in this class of disorders. It must be obvious, however, to all who have observed the very different forms, the varying phases, and the numerous complications of these disorders, — who have viewed them in connection with their causes, and with their effects upon the organisation,— that they, of all maladies, require not only the most diversified, but also the most opposite means, according to the different *causes* and *kinds* of disorder, and to the changes observed in particular cases.

387. Each case of mental disorder presents certain circumstances, all which require calm consideration, in order that it may be successfully treated. —1st. *The causes*, whether moral or physical, predisposing or exciting, should be viewed, in respect of their individual and combined operation, — of their action on the system generally, and on the brain, or any other organ particularly, — and whether acting primarily and immediately, or secondarily and sympathetically. — 2d. *The state* and *stage of morbid action* ought to be ascertained, as regards both the grade of action, generally and locally, and the influence which such action seems to exert upon the manifestations of mind; —and, 3d. *The condition of the organic functions*, not only as it may be the cause of general and local morbid action, but also as it may be the consequence of such action.— On these circumstances are based those indications of cure which should be proposed when entering upon the treatment of every case of mental disorder. — 1st. *The causes should be removed, in ways appropriate to their nature and combinations.* — 2d. *General or local morbid action ought to be moderated, controlled, or removed according to its nature — whether it be increased or excited, or imperfect, or deficient.* — 3d. *The several organic functions should be promoted, when impaired; and restrained, when inordinately excited, either individually or collectively.* It is unnecessary to state here, how these intentions are to be severally carried into effect. The method or plan of procedure must necessarily vary with the circumstances characterising the different forms of the malady, and the individual cases of these forms; but the remarks which I have to make may be referred to each of these indications, and in their respective order.

388. *A. The seclusion of the insane* is a question of the first and greatest importance, not merely as respects the removal of the causes of disorder, although this is one of the chief points in which it should be viewed, but also as regards the physical and moral treatment. That every person who is more or less disordered in mind should be separated from those with whom he has been accustomed to live, and from his family and friends, and restrained from his accustomed habits and manners, and confided to the care of strangers, in a place altogether new to him, may not be affirmed universally; but the exceptions to this rule are not numerous, and should be made, in practice, with care and discrimination. As to the propriety of this measure, the most experienced physicians in Great Britain, and in foreign countries, are agreed. M. ESQUIROL remarks that recoveries are comparatively more numerous amongst the patients who come to Paris to be treated, than among those who inhabit that capital; for the latter are less completely isolated than the former.

389. *a.* The first effect of this measure is to produce new sensations, to change or to break the series of morbid ideas of which an insane person cannot divest himself: unexpected impressions are made upon him, arrest and excite his attention, and render him more accessible to counsels which may restore his reason. Generally, as soon as he is thus secluded, he is surprised and disconcerted, and experiences a remission of the disorder, that is of the utmost consequence in the treatment of it, and in acquiring his confidence. The change is not the less useful, observes M. ESQUIROL, in combating the disorder of the moral affections of the insane. The disturbance of the nervous system renders the sensations morbid and often painful; their natural relations with the external world are no longer the same as in health; all things seem disordered or overturned. The patient cannot believe that the cause of these phenomena is in himself. He is persuaded that every one wishes to contradict and irritate him, because they disapprove of his excesses: not understanding what is said, he becomes impatient, and puts an unfavourable construction on what is addressed

to him. The most tender expressions are taken as offences, or for enigmas that he cannot comprehend. The most assiduous care is vexatious to him. The insane patient, having become timid or sullen, suspects every one who approaches him, and especially those who were dearest to him. The conviction that every one is inclined to torment, defame, and to ruin him, increases the moral disorder. With this symptomatic suspicion of those about him, — which generally increases, without any motive or cause, from inevitable circumstances or opposition, and with the change in the intellects, — to allow the patient to remain in the bosom of his family might soon be followed by the most disastrous consequences, not only to himself, but also to others.

390. Where the husband suspects the cares and assiduities of the wife; or the wife those of the husband; and supposes that he or she is in league with those who conspire against him; — where the lunatic believes that the members of his family are the slaves destined to obey his sovereign commands; or are the ministers or apostles of his mission; — where the cause of the mental disorder exists in the patient's own family, or arises from dissensions, chagrins, reverses of fortune, or privations; — where the insane person entertains an aversion, hatred, or dislike to any member of his domestic circle, and, particularly, to any one who had been most dear to him; — or where the parent, or the son, the lover, or the friend, is impressed with the sentiment of his incapability of fulfilling the duties which he conceives to be imposed upon him, — the necessity and advantages of removal, and complete separation, from the object of his aversion, of his anxieties, or of his fears, are especially obvious and indisputable. The dislike entertained by the insane to those who had once been most dear to them, without either cause or motive, imperatively demands the removal of the patient, who generally readily becomes calm before, or attaches himself to, an agreeable stranger, owing either to the circumstance of his presence being unattended by any unpleasant association or suggestion, or to a feeling of self-love which induces him to conceal his sentiments and his state, or to the novelty of the impressions produced by strange persons and objects.—Whilst these are the chief inconveniencies and difficulties in the way of the treatment of the insane whilst they remain in the bosom of their families, there are great advantages to be derived from removal to a place suitable to the management of this class of patients.

391. *b*. But how should the seclusion or the separation of the insane be carried into effect? That it should be effected by means of an asylum or institution devoted to their treatment, in the great majority of cases, is generally admitted; although removal to such a place may be unnecessary in some instances, or unadvisable in others, owing either to the character of the disorder, or to the peculiar position of the patient — to the circumstances connected with certain cases. *Partial seclusion* or separation may be resorted to in some cases, and especially in those which are slight. A partial separation is when the patient remains in his own house, and is separated either partially or altogether from the members of his family and his friends, and is placed in the care of one or more suitable persons. Seclusion is more complete when he is sent to travel, or to make a voyage, in the custody of proper persons, or of one or more of his relations or connections. And it is *complete*, when he is removed to a residence altogether new to him, and surrounded by strangers, to whose care he is committed. Of this last kind of separation, there are several modifications; the chief of which are — 1st, A private residence, devoted to the patient and to those placed in charge of him; — 2d, A private asylum, containing several or many inmates; — and, 3d, A public, or large institution destined to the reception of a great number. In the great majority of cases, the seclusion, in order that it may be fully successful, should be complete; and the last of these modes, when provided with all the appliances and advantages which many of these now possess, is the most useful, as it conjoins, with complete separation from the relations of the insane, several arrangements and circumstances obviously beneficial. M. Esquirol remarks that the patient should be removed to an institution devoted to the treatment of mental disorders, rather than to a private asylum or residence. Partial isolation is much less successful, than that more completely afforded in a well regulated institution. The chief objection which has been urged against the latter, is the association with a number of companions in misfortune: but this is not injurious, is no obstacle to recovery, but is even of service, inasmuch as it causes the patient to reflect upon his condition; and, as the objects around cease to impress him, he is amused or distracted by those about him, is occupied by the objects passing around him, and thereby abstracted from what is apt injuriously to engage his thoughts. Large institutions, moreover, present greater facilities for the protection of the maniacal and furious, without having recourse to injurious or irritating means of coercion and restraint; and the attendants are more experienced in their management, than in a private house of detention. The advantages, however, of treatment in institutions of this kind depend entirely upon the medical acquirements and the characters of those intrusted with their management; upon the nature and completeness of the arrangements, therapeutical, hygeienic, and moral; and upon the organisation and discipline of the whole establishment. Still, there are cases, to which removal to institutions or asylums for the insane is not applicable, however ably they may be managed, and their inmates treated; and, to these cases especially, removal thence might be productive of injury, particularly if the seclusion were not modified according to the susceptibility of the patient, to the character of the disorder, and conformably with the passions, the habits, the feelings, and the modes of living and manners of those subjected to it. It is not to be considered as a measure which should be universally employed. In this, as in all other departments of medical practice, experience — that is, close observation of phenomena, a knowledge of all matters related to individual cases, and a comprehensive view, and weighing of circumstances — will generally decide correctly as to its propriety.

392. Example, which has so great power over the opinions and actions of man, also influences the insane, who are often not deficient in sagacity and in the power of comprehending what is passing

around them. The recovery, or the departure of a patient, creates confidence in others, and a hope of recovery, and restoration to liberty. The convalescents, by their conduct, and advice, console and encourage those who suffer, and thus are of the greatest benefit; one class of inmates of such institutions acting beneficially on the other, and favouring the success of the treatment. The calm, also, enjoyed by all; the moral repose arising out of removal from the habits, the business, the perplexing cares, the domestic anxieties and chagrins, and the irritating contrarieties, to which they were previously exposed; the regular mode of living, the judicious discipline, and the regimen, to which they are subjected; and the necessity of duly comporting themselves—of conducting themselves with propriety before strangers, and before one another, — all tend to suggest rational reflections; and become powerful auxiliary means of recovery. The cares and attentions which the insane receive in their own families are counted as nothing; but the attentions paid them abroad, or by strangers, are appreciated, because they are novel, and are neither due nor exacted. Hence the control readily obtained by those to whose care they are committed, when they are kindly and judiciously treated.

393. *c.* For melancholic and various forms of partial or slight insanity, complete separation is sometimes unnecessary, or even injurious. Partial separation, travelling, and various modes of exerting moral control, according to the peculiarities of the case, are often best suited to these states of disorder. Mania, and several states of monomania, demand complete seclusion. Dementy, imbecility, and idiotcy require more or less complete separation — at least from society. Complete seclusion is generally necessary to the poor lunatic; as he would otherwise be unprovided with the aid required to restore him to his family.

394. *d.* Separation and isolation act directly on the brain, — composing it to tranquillity, shutting out irritating impressions, repressing excitement, and moderating the exaltation of the passions and ideas. The sensations of the maniac are thereby reduced in number and intensity; and his attention arrested, and even fixed, by thus being reduced, by the novelty of those which are excited, and by their frequent repetition. The melancholic and monomaniac are torn away by it from their morbidly concentrated thoughts and ideas, and are directed to different objects or topics, — especially when proper means of distraction are had recourse to — when judicious moral management is conjoined with enlightened medical treatment.

395. *e.* In separating the insane from their families, the place of residence selected for them should be healthy, airy, and protected from cold winds, as well as from humidity and offensive exhalations. Their constitutions are generally more or less impaired and enfeebled, and they are consequently the more obnoxious to depressing influences and contaminating agents. They are generally predisposed to cutaneous eruptions, enlargements of the glands, and general cachexia; and they therefore require the more a dry and temperate, or even moderately warm, air. It is a grievous mistake to suppose that they are insensible to cold and atmospheric vicissitudes. Although they may not give expression to their sensations, their constitutions, and even the states of their minds, are remarkably affected by cold, humidity, and sudden changes of weather and season, — against which they should be completely protected.

396. *f.* The period at which the seclusion of the insane should terminate, is not easily determined. Experience of a diversity of cases and circumstances is the chief guide to a just conclusion. When this measure is found to be unavailing, after having been duly employed, the visits of near relations, friends, or former connections, may be tried; great discretion being used in the selection of those who are the first to be admitted to the patient. In such cases, the visit ought to be sudden and unexpected by him, in order that it may make the stronger impression. The utmost care should be taken in the admission of the visits of friends to convalescents; and, with them, suddenness and surprise should be guarded against. Upon the whole, it is preferable that seclusion should be prolonged, rather than that it should cease prematurely. This measure, moreover, ought not to be had recourse to in any state of delirium consequent upon, or symptomatic of, febrile diseases; and seldom in puerperal insanity.

397. *B.* To establish *the medical treatment* upon a sure basis, it is necessary to obtain as complete a knowledge as possible of the predisposing and exciting causes of the malady; to ascertain the physical as well as the moral sources and relations of it; to determine whether the physical occasions the moral, or the moral causes the physical, derangement; and to recognise the cases which will recover spontaneously upon separation or isolation and upon the removal of the causes, those which require chiefly judicious moral management, those which demand medical treatment, and those for which a combination of these means will be requisite. Regardless of these and various other important considerations, the medical treatment of the insane has too generally been conducted either empirically, or in the spirit of a narrow and exclusive system. Influenced by theory, or a predominant doctrine, some have referred mental disorders to inflammation, and have abused the various modes of blood-letting; others have believed that these disorders proceed from a morbid state of the biliary and digestive functions, and have disordered still more these functions and their respective organs by emetics and drastic purgatives; and many have considered the nervous influence solely in fault, and have attempted to correct it by means of antispasmodics and stimulants: hence the treatment has been nearly as often prejudicial as beneficial; and recovery has taken place, in many instances, *notwithstanding* the means that have been used, rather than *by the aid* of them.

398. *a.* When called to a case of insanity, the obvious duty of the physician is to ascertain the predisposing and exciting causes; the several circumstances co-operating with these causes, or contributing to their influence and intensity; the particular form or character of the disorder, its duration, and physical relations; the states of the several functions, organic and cerebro-spinal, and the connection that may exist between the mental disorder and the states of these functions, or of their respective organs. He will, moreover, observe whatever may exist of a pressing nature, or whatever indication there may be urgently re-

quiring to be fulfilled; as, for example, whether or not the signs of vascular determination to, or excitement in, the brain be obvious, and indicate impending risk to the organ; whether there be general vascular plethora or vascular inanition; whether some accustomed discharge, evacuation, or eruption has been suppressed; and whether or not the patient has been subject to some constitutional disorder, as gout or rheumatism. It is manifest that these are matters most necessary to be known, upon commencing the medical treatment of every case of mental disorder; and, without they are assiduously investigated, in no one instance can such disorder be appropriately treated. Where these more urgent indications exist, they require instant attention; — where the blood is strongly determined to the brain, the usual means of subduing the morbid action — local depletions, the cold affusion, or tepid douche or shower bath, external and internal revulsants and derivations, suitable diet and regimen, &c. — are requisite; — where the vascular system is plethoric or inordinately excited, sanguineous depletions, refrigerants, sedatives; evacuations from the bowels, the skin, and urinary organs; and low diet, are necessary; — where the catamenial or the hæmorrhoidal discharges, and eruptions or evacuations, either sanguineous or serous, or of other characters, have been suppressed, or have ceased to appear after the accustomed interval, the most active means must be prescribed, in order to reproduce them, or as substitutes for them.

399. *b.* Having removed the causes and concurring circumstances of the malady, — having thus fulfilled the more urgent and pressing indications, — and having remedied such morbid conditions of the organic functions as may have existed, — the more acute symptoms or stage of the malady will subside in about 8, 14, 21, or 28 days, or generally within 40 days, and a remission, or even an intermission, will occur. At this period, judicious and appropriate moral means should be brought in aid of the physical treatment; whilst the causes, moral, hygeienic, and pathological, ought to be removed or combated. If the recovery does not proceed satisfactorily, — or if these means, varied according to the particular circumstances of the case, do not produce beneficial results, — other remedies, sanctioned by experience, must be tried. These, however, will be fully noticed in the sequel.

400. *C.* As the malady thus lapses into a more or less *chronic form*, local or general manifestations of morbid action, which occasionally appear, return, or even remain, should be removed or suppressed by the usual and generally obvious means; and signs of disordered sensibility should be traced to their sources, and their pathological causes removed. Whenever disorder or disease of any organ in the abdominal or thoracic cavity is evinced, the fact of such disorder being frequently connected, either as cause or effect, with that state of the brain which occasions the disorder of its associated mind, should be kept in recollection; and an appropriate treatment ought to be directed to the quarter thus manifesting disordered sensibility or function, — always bearing in mind that morbid action in the substance of the brain is more frequently indicated by morbid sensations and disordered movements and functions in remote than in adjoining parts.

401. During the whole course of the treatment, the several organic and reproductive functions require attention. The state of the digestive organs, and especially of the biliary and the intestinal secretions, — and, indeed, the whole of the excretory functions — the fæcal, the urinary, and the cutaneous, — ought to be duly, or even daily, observed, and promoted whenever scanty or suppressed, or restrained when they become so excessive as to debilitate. More frequently, especially at the earlier periods of the malady, these functions require to be promoted; and as the defect, as well as the disorder, of these functions is often owing to impairment of the organic nervous or vital energies, the restoration of their healthy states should be attempted chiefly by means which will also invigorate these energies. With this intention, stomachics, tonics, or restoratives should be conjoined or alternated with purgatives, chologogues, or alteratives; and the bowels ought never be allowed to be confined, or the biliary secretion to be deficient. The appearances and the sediments of the urine should be ascertained, and alkalies or acids administered accordingly, with gentle stomachics and diuretics; and the action of the skin ought to be duly regulated by the cold, the shower, the tepid, or the warm bath, and by frictions and clothing, according to the form or stage of the malady, and the particular conditions of the cutaneous function. The states of the reproductive organs also require observation — especially of the uterus. And it should not be overlooked, that these organs are often abused by solitary indulgence, in such a manner as both to cause and to perpetuate the malady. Where this is detected, or even suspected, means should be contrived to prevent it. In advanced stages of insanity, although the treatment should be conducted, with reference to the removal of existing pathological states and of disordered mental manifestations, according to rational principles; still, when means thus devised fail of success, other and more empirical remedies, sanctioned by experience, ought not to be neglected. To these, however, sufficient reference will be made hereafter.

402. *D. The clothing* of insane persons, particularly of the melancholic, should be warm. In general, flannel may be worn next the surface; and dry friction every morning will be useful. The patient should sleep on a hair mattress, and hair pillow. His head ought to be somewhat elevated, and generally uncovered. The insane epileptic ought to sleep in a very low bed, to prevent accidents during a paroxysm. The propriety of devoting strict attention to cleanliness, in respect both of his person and clothes, is obvious.

403. *E. The food and diet* of the insane must necessarily be varied with the nature, complications, and stage of the disorder, and with the circumstances of particular cases. In the more acute attacks or stages of the malady, the diet and regimen ought generally to be antiphlogistic; at a later period, and in more chronic cases, and particularly in states evincing vital depression or exhaustion, the food should be more nutritious, in larger quantity, and easy of digestion; but hot spices and stimulants ought not to be allowed. During convalescence, the diet may be more substantial, but not heating; and duly regulated according to the exercise that is taken.

The meals should be at regular periods, and deliberately partaken of, and well masticated. A sufficient quantity of fluids should be allowed to assuage the thirst of the patient, which is generally urgent in mania, and in some cases of monomania; but they ought not to be given, unless when necessary, or when, in certain cases, a profuse use of them forms a part of the treatment.

404. *F. The management of convalescence* is one of the most difficult parts of the treatment of the insane. If the patient be not placed in favourable circumstances for some time after the subsidence of the malady; if he be not carefully and kindly watched; if contrarieties of mind, family dissentions, and all the remote causes, moral and physical, be not sedulously avoided; and if the diet, regimen, and mode of living be not suited to his constitution and the peculiarities of his late disorder, — the risk of a relapse will be great. At this period, and for long afterwards, much mental exertion or application, sudden bursts of passion, and excesses of every description, must be shunned; and the earliest manifestation of physical disorder — of headach, of disorder of the digestive organs, and of interruption of accustomed evacuations or discharges — should be met with local depletions, purgatives, revulsants, diaphoretics, and other means appropriate to the nature of the disorder. As convalescence proceeds, change of air and of scene, and travelling with a suitable companion, or one capable of amusing, fortifying, and even of controlling the mind, will be most beneficial; and such mineral waters as will promote the secretions and excretions, and at the same time strengthen the constitution, without exciting or heating the circulation, or determining the blood to the head, will often prove of essential service.

405. *G. The measures proper to prevent insanity, and more especially a relapse or return of it*, are most obviously presented to the reader in the full exposition I have given of the predisposing and exciting causes. The avoiding of these constitutes the chief, and, indeed, the only, *prophylaxis.* Young persons, whose parents have been the subjects of this malady, should have especial attention paid to both their physical and their mental developement; and whilst the former is promoted by exercise in the open air, and healthy occupation, the latter should be cultivated, without being over-exerted, and sound religious and moral principles ought to be inculcated; care being taken to avoid indulgence of the caprices, passions, and selfish feelings. The instruction of these persons should not be premature; but the desires and passions ought to be early restrained. The judgment should also be early and judiciously informed, without fatiguing the mind; and the control of parents or guardians ought to be prolonged for a considerable period after puberty, and until the mind, conduct, and constitution are fully formed.

406. ii. OF THE TREATMENT OF THE SPECIFIC FORMS OF INSANITY. — *A.* PARTIAL INSANITY. — *The simpler forms or slighter grades of insanity* severally require a moral management, as well as a medical treatment, appropriately directed to their different states and characters, — which, however, are so diversified as to preclude the possibility of my considering the subject with reference to any but those which are the more common and prominent. — *a. In the various states of moral insanity* (§ 69. *et seq.*), in which the patient is not labouring under any illusion, or erroneous conviction, or disorder of the understanding, the propriety of *seclusion* cannot be decided upon, excepting with reference to the features of, and the circumstances connected with, individual cases. Many of these states of moral disorder, consisting chiefly of errors in action and conduct, are not of that grave and well-marked kind which is considered in the eye of the law to require the privation of liberty; although, in the majority of such instances, the conduct of the patient may be such as will prove the most injurious to himself and to those depending upon him. In other less questionable cases of derangement, and where the disorder is so restricted as to leave the patient, according to appearances, the exercise of a great portion of his reason, it is often difficult to come to a determination as to the propriety of seclusion. The opposition which the patient may experience, may endanger the portion of intelligence that remains. It is as unnecessary as it is cruel, to deprive a person oppressed by distressing feelings, or prone to terror or alarm, of his friends and relatives — of the attentions of his family — as long as he entertains no vindictive feelings or dislike to them, and especially as long as his actions may be reasonably controlled by them.

407. *α.* In the state of gloom and mental depression to which some persons, the subjects of moral insanity, are prone (§ 73.), seclusion may be productive as readily of mischief as of benefit. For these, travelling, visiting watering places, medical treatment, the kind intercourse of those to whom the patient is partial, and the watchful attentions of the members of his family, or of those accustomed to attend upon persons in this state of mental affliction, should be tried before seclusion be resorted to. When suicide is contemplated, seclusion and control in an asylum will prove more successful than the most careful attentions in the bosom of the patient's family. Still, in the majority of such cases, this measure will be more successful chiefly in respect of the safe custody of the patient; for none besides will be equally secure. The most vigilant keepers may be deceived by him, when he is otherwise at large.

408. *β.* When the disorder is characterised by unnatural excitement (§ 74.), seclusion and confinement are often requisite, and are generally successful by inducing reflection. When persons thus affected have a propensity to intoxicating liquors, accessions of mania being thereby occasioned, seclusion is necessary; but upon the restoration of liberty the morbid disposition returns. In all cases of moral insanity where the morbid propensity is dangerous to the patient or to others, this measure becomes indispensable. When the disorder assumes a religious character (§ 75.), travelling, society, and a suitable moral and medical treatment, are preferable to seclusion; and confinement ought not to be resorted to, unless suicide have been attempted or contemplated.

409. The treatment of all the forms of moral insanity ought to be essentially, although not exclusively, *moral.* Comparatively few instances of these do not present more or less of physical disorder, seated either in the head itself, or in

some organ with which the brain sympathises. Of this I have already adduced sufficient evidence (§ 92—94.). The moral treatment, in all these, must be based upon a knowledge of the remote causes of individual cases, and should vary with the circumstances of each. It is impossible to state here in what this treatment should consist, with reference to such circumstances: the subject will be as fully treated of hereafter as my limits will permit. Wherever physical derangement can be detected, or to whatever organ it can be referred, appropriate medical means should be directed against it, whilst the patient is enjoying the advantages of a suitable moral management. The general health should receive due attention; and the functions of digestion, secretion, and excretion be duly promoted. Due restraint ought to be, as far as possible, imposed upon the passions and emotions; and change of air, wholesome exercise, and interesting occupations be prescribed.

410. γ. *The treatment of erotomania* should have reference chiefly to disordered circulation in the brain occasioned by an excited imagination and protracted desire, in connection with great susceptibility of the nervous system generally. If this affection be not alleviated, it will pass into more general disorder of the mental powers — especially into melancholia, mania, or some form of dementia. When it occasions emaciation and hectic fever, thereby menacing the life of the patient, marriage may be suggested. In this, as in nostalgia, the accomplishment of the desires of the patient is the chief or only remedy. When the object of desire is concealed, every art should be tried to ascertain its nature and source; as the effects upon the mind that will consequently result may be of much service, and a moral influence may be exerted over the patient with greater advantage. Where marriage is impossible, change of scene, travelling, society, and the amusements of watering-places, a tonic and restorative treatment, healthful and pleasant occupations, exercise in the open air in agreeable company, and suitable diet and regimen, are chiefly to be depended upon. When there is any evidence of increased determination of blood to the head, in this, as in other forms of moral insanity, and especially when the scalp is hot, or the eyes injected, the tepid or cold shower bath every morning will be found of great service.

411. δ. *The morbid propensity to intoxication* (§ 86.) is often attended by symptoms indicating not only a state of irritation of the stomach, but also a general depression of the nervous power. In this state, tonics, with small doses of ammonia, may be used with advantage; and, in order to counteract the injurious effects of the intoxicating fluids upon the system, to prevent the disorder from leading to more general and severe derangement of mind, and to disgust the patient with these fluids, tartarised antimony, ipecacuanha wine, or other nauseating drugs, and even the extract of elaterium, or croton oil, may be added to them before they are partaken of by the patient. In two cases, one of which I attended with Mr. Hood, this method was found successful in causing a loathing of these fluids, in moderating the mania consequent upon the use of them, and in permanently restoring the patients. In both these cases, seclusion, and a sufficiently permanent and close restraint, could not be conveniently put in practice: this plan was, therefore, tried in the first instance, and succeeded in causing a distaste of all kinds of intoxicating liquors. To succeed, however, by means of it, requires great care and management on the part of the friends of the patient.

412. ε. *Homicidal insanity* (§ 89.) *and incendiarism* (§ 88.) are generally dependent upon an irregular activity of the circulation, or a morbid state of vascular action — especially in the brain. They are both frequently connected with disorder of the uterine organs, or suppression of the catamenia; and, in males, with derangement of the digestive organs, and with sanguineous determination to the head. Medical treatment in these cases is mainly to be trusted to; for the morbid impulse to commit these crimes is often so violent as to be instantly carried into effect, either before moral restraint can be exerted to counteract it, or because this restraint is habitually so feeble as to be inefficient, or is not roused to the least degree of activity. The impulse to perpetrate such crimes may, indeed, be looked upon as one of the modes in which physical disorder of the brain, arising either primarily or sympathetically, deranges the manifestations of mind,— those sentiments or propensities which circumstances have called into activity being thereby disordered or morbidly exalted. In many instances, also, there is reason to believe that the morbid impulse to commit crime is only the climax of an habitual indulgence of passion and feeling, to the constant neglect of moral principle and restraint; and is a tolerably obvious consequence of cerebral excitement, the effects of which are determined or manifested in this particular manner or direction, owing to various predisposing and concurring sentiments and circumstances.

413. In these cases, local or general depletions, according to the amount of local or general fulness, or of increased vascular action; the cold douche, cold affusion, or shower bath; active purgatives, revulsants, and derivatives; antimonial and other diaphoretics; digitalis and other sedatives; and the promotion of the secretions and excretions generally, — constitute the chief principles of treatment; aided, however, by a due moral influence, and by proper mental and physical occupation.

414. *b. Partial disorder of the understanding* (§ 95.) appears under so various and numerous forms as to require a treatment appropriate not only to each of these, but also to individual cases. Each patient should be a particular subject of study, and the moral and physical treatment directed according to the character and stage or duration of the disorder, and the various circumstances connected with its developement. — *a. Hypochondriacal monomania* is generally an extreme state of *hypochondriasis*, and more or less intimately connected with physical disorder, commonly commencing in the digestive organs, and consecutively affecting the brain. The treatment should not be materially different from that which I have recommended for that disease; and the *hygeienic means* there advised (see Hypochondriasis, § 50.) especially should be adopted. In the majority of cases, complete seclusion will not be necessary, unless the patient contemplate or attempt suicide. More generally, however,

travelling, change of scene and of air, horse exercise, agreeable occupations, hunting, the amusements of society and of places of resort, — especially when attended and controlled by friends or suitable persons, — will be found most conducive to recovery, particularly if an appropriate medical treatment, and the use of mineral waters of a restorative and deobstruent or laxative kind, be pursued at the same time. Every method should be tried, and especially those just mentioned, to abstract or seduce the patient's attention from those feelings and ailments with which his mind is exclusively and morbidly occupied. The strictly medical means should be varied according to the peculiarities of individual cases; and the more urgent symptoms should be palliated by suitable remedies. The bowels ought never be allowed to become costive, and their functions should be promoted by aperients, conjoined with tonics, carminatives, and deobstruents. All the secretions and excretions should be duly promoted. Flatulence and gastrodynia must be allayed by magnesia, the hydrocyanic acid, gentle tonics, &c. variously combined; and by spare diet, consisting chiefly of warm milk, with bread or boiled rice, or other farinaceous articles.

415. *β. The treatment of melancholic monomania* (§ 106.) is most difficult; and, to be successful, requires a strict examination of the physical and moral causes of each case, and an appropriate employment of moral, hygeienic, and medical means.—(*a*) *Moral treatment* is of the greatest importance in this form of insanity, and in all its modifications, whether religious, or demonomaniac, or misanthropic, melancholia, or any other it may assume; but this part of my subject will be more appropriately considered hereafter.

416. (*b*) The *hygeienic measures* that may be resorted to, consist chiefly of attention to climate, residence, exercise, clothing, and diet. The patient should *reside* as much as possible in a moderately warm, or temperate, and dry air, or in a mild climate and a clear atmosphere; and if he must abide for a time in a place where these advantages are not enjoyed, he should choose spring and summer, and migrate during autumn to the milder climate, where he should reside during the winter and early spring months. The patient's *clothing* should be warm, and consist of flannel nearest the skin; and this should be frequently changed. As melancholics are subject to cold feet, these parts should be carefully protected.

417. (*c*) *Seclusion*—at least, complete seclusion — should be prescribed with great circumspection. There can be no doubt of its propriety when suicide is contemplated, or has been attempted. But in other cases, partial seclusion, particularly in connection with agreeable and interesting occupation, and amusement, is more safe and beneficial. Seclusion, however, even when complete, often re-establishes the moral powers, and the reasoning faculties, when they are exhausted by indulgence of the passions and desires.

418. (*d*) *Exercise* and suitable *occupation* are very important parts of the treatment of melancholia, and of all the states of partial insanity. Travelling, voyaging, — especially to a considerable distance, and with a fixed object, or with feelings of interest in what may result or occur, — is one of the best means that can be devised. Exercise on foot or on horseback, regularly taken, so as to promote the cutaneous excretion; occupations in the open air, which are attended by moderate physical exertion and mental excitement; hunting, shooting, and games of skill and activity, as cricket; and farming and gardening,—are severally of great benefit. The chief objection to the last of these, is the occasional stooping necessary to several of its duties. Billiards are also useful means, both of exercise, interest, and amusement. Whatever moderately excites, interests, and occupies the mind, is serviceable in the treatment of melancholia; and especially if it at the same time abstract the attention or imagination from the object of its illusion. When *music* is properly selected, and prosecuted so as to accomplish these objects, the advantages that may be derived from it are great. As to the selection of modes of occupation and exercise for individual cases, much should depend upon the patient's previous and existing tastes and habits. A principal intention in this class of disorders — in all forms of partial insanity — is, to detach the patient's attention, his mental devotion, from the object on which he has morbidly fixed it, to seduce it to other objects, and to engage it with different subjects and matters of interest and importance.

419. (*e*) *The diet* of melancholic patients should be light, digestible, and moderately nutritious. Salted, highly spiced, irritating, and oily or fat articles of food ought to be always avoided. The food should be simple, plainly dressed, consisting of very few articles at the same meal. Ripe and fresh fruits, in due season, may be allowed. The quantity and kind of food should have reference to the amount of exercise. When this is so great as to freely promote the cutaneous, biliary, and alvine evacuations, a more liberal diet may be permitted than in other circumstances. Great circumspection is requisite in allowing this class of patients restorative or exciting liquors. If the head be cool, and the action of the carotids rather below than above the healthy standard, these may be tried in small or very moderate quantity, and their effects observed. Generally, however, the influence of gentle tonic and restorative medicines should be previously tried.

420. (*f*) *Medical Treatment.*—The physical disorder requires, simultaneously with the adoption of the foregoing measures, and of suitable moral means, a judicious recourse to remedies calculated to promote or to correct the functions of the digestive organs, and, indeed, of all the abdominal viscera. There are very few of these viscera which have not betrayed more or less of disorder even long previously to the developement of the mental affection. The functions of the skin are usually impaired, and often require the tepid or the warm bath for their restoration. The alvine excretions— especially the intestinal — are generally retained, or voided imperfectly or with reluctance, owing manifestly to relaxation of the muscular tone of the bowels, and especially of the colon. The secretions are also deficient, and morbid from their retention. These physical conditions require for their removal the frequent use of aperients and laxatives, conjoined with tonics and other restoratives; for their continuance would increase that state of excrementitial plethora of the vascular system in which melancholia and hypochondriasis often originate, by depressing and disordering the vital manifestations of the brain. Even the urinary

secretion is deficient; the discharge of the more excrementitious materials from the blood by the kidneys being partially interrupted, or deficient in respect of certain of the constituents of the urine. In most instances, the morbid materials carried into the circulation, or accumulated in it, owing to defective powers of digestion and assimilation, are not sufficiently discharged from it by the action of the kidneys, bowels, liver, and skin; and thus the impure state of the blood influences the manifestations of the nervous centres. In such circumstances, the restoration of these functions by suitable hygeienic and medical treatment is always a principal indication of cure.

421. The chances of recovery from melancholia may be almost said to be great in proportion to the manifestation of disorder in the organs of digestion. As the pathological causes of the mental affection show themselves the more evidently, the greater hopes may be entertained of the disappearance of the latter with the removal of the former. Where these exist, the therapeutical intentions should be directed accordingly. If the function of any organ be impaired or interrupted, the restoration of it is indicated; — if the hæmorrhoidal or catamenial evacuation is suppressed, means should be taken to re-establish it; — if a cutaneous eruption have disappeared, or an accustomed ulceration or issue ceased to discharge, the skin should be acted upon, or some analogous mode of derivation and counter-irritation be adopted. It is, however, not always, nor even frequently, that melancholia can be referred to these, or equally manifest sources, and where such very obvious indications of cure as these present themselves. Still, there are generally to be observed certain conditions of the abdominal organs, of the cerebral and general circulation, and of the nervous system, which severally require attention, and furnish the basis of a rational method of treatment.

422. Where the functions of the digestive organs are sluggish, the bile is morbid, dark, irritating, or scanty, and the various secretions and excretions insufficient for the due purification of the blood, or for the preservation of it in a healthy condition, it is clearly indicated to restore these functions by means which shall impart a new impetus to the vital endowment of their respective organs, and enable them regularly to perform their offices. In a very large proportion of cases, not only is the bile morbid, but the whole abdominal secretions are disordered; and certain of them are retained on the intestinal mucous surfaces, or even accumulated in the cæcum and colon. The frequency of these changes, and the benefit resulting from the more certain means of removing them, induced the ancients to have recourse to black hellebore; and the moderns to milder cathartics, to purgatives, or to laxatives, in the treatment of this malady; and the propriety of the practice, when the means are well selected and combined, and judiciously managed, cannot be disputed. In some cases, — especially where there is much torpor of the biliary apparatus and of the bowels, with accumulated sordes on the digestive mucous surface, — a brisk *emetic*, or even an *emeto-cathartic*, is of great service early in the complaint, and at the commencement of the treatment. When the strength of the patient will permit, a continued action on the bowels — an artificial diarrhœa — should be kept up, by means of chologogue or stomachic purgatives or aperients, for a considerable period; and purgative enemata may also be employed. A combination of the compound infusions of gentian and senna, with a neutral salt, and an aromatic spirit or tincture (F. 266.), will be appropriate in these cases; and the spirit of turpentine, with castor or olive oil, may be prescribed in enemata. A similar means to these, of which a variety will be found in the *Appendix*, and in the articles Hypochondriasis and Indigestion, may be employed according to the peculiarities of individual cases. When the patient believes that his physical health is not in fault, or when there is a disposition to sanguineous determination to the head, James's powder, or tartarised antimony, may be given in small and frequently repeated doses, so as to keep up an action upon the skin or bowels, and to induce a feeling of bodily ailment, so as to dispose the patient to pursue a suitable treatment.

423. When indications of congestion of the brain, or of determination of blood to this part, or of general vascular plethora, or of inflammatory irritation of the gastro-intestinal mucous surface, or of fulness of the portal system, are observable, — and especially if they have become more evident after the disappearance of an accustomed evacuation, — general or local bloodletting should not be delayed. Local depletions are generally most appropriate in these circumstances, and ought to be decidedly employed — particularly in the more robust. Aretæus permitted bloodletting only in the young and robust, in this complaint, and in small quantity, and chiefly in spring; Cullen considered that it was rarely useful; Pinel seldom employed it; and Esquirol advised it in nearly the same circumstances as I have recommended it. The application of leeches, and even the repetition of them, to the vicinity of the vulva, or around the anus, when the catamenial or hæmorrhoidal evacuations have been interrupted, or the portal system congested; and to the epigastrium or hypochondria, or behind the ears, when uneasy sensations are referred to the enclosed organs, — is generally attended with benefit; and this evacuation may be repeated even oftener than once, and commonly with advantage, although it may be requisite to administer tonics, antispasmodics, or restoratives, at the same time.

424. Many cases of melancholia present a morbid susceptibility and sensibility of the nervous system. The patient is remarkably nervous; and his distress is evidently heightened by sanguineous depletions, however moderate; and by purgatives, if too frequently exhibited, or even if they operate beyond the mere evacuation of the bowels. Lorry has well described this form of melancholy; and very properly recommended for it calming measures, — opiates, with gentle stimulants and restoratives. In these cases, the warm or vapour bath, the tepid or warm douche, the affusion of warm or tepid water on the head, and the tepid bath, according to circumstances, will be of great service. Small doses of camphor, with opium, morphia, or hyoscyamus, or with the extract of poppy or lactucarium; the infusion or the ammoniated tincture of valerian, or both conjoined; the infusion or tincture of hop; and other antispasmodics and diffusive stimulants, va-

riously conjoined with sedatives, narcotics, &c., and a pure dry air, change of scene, and light food, — are generally beneficial in this state of disorder. If there be watchfulness and irritability, the hop-pillow, or the syrup of poppies, or the compound tincture of camphor, in a small enema, will afford relief. When the disorder has been caused by masturbation, the cold affusion or shower bath, the cold plunge bath, and tonics, — especially the muriated tincture of iron, — should be prescribed. As the energy of the nervous system returns, more permanent and energetic restoratives and tonics may be employed; but, during their use, the secretions and excretions ought to be carefully promoted, and the bowels kept freely open; care being taken to prevent congestions of the brain or portal system.

425. In many instances, a combination of the several indications based upon the conditions of the abdominal organs and of the vascular and nervous systems, and the association of more or less of the means required to fulfil these indications, are often both necessary and successful. Thus, it is frequently of the greatest advantage to act energetically upon the bowels by means of stomachic or chologogue purgatives; to deplete the vascular system, either generally or locally; and, at the same time, to give stimulants, antispasmodics, and tonics; the choice of the several means depending upon the characters and symptoms of individual cases. As to the propriety of exhibiting the more active tonics in melancholia, much doubt may be entertained: but if accumulations of morbid matters in the bowels have been removed; if the tongue be clean, moist, or watery; if the secretions and excretions have been improved; and if a trial of them be not productive of headach, of increased heat of the scalp, or of feverishness, — the use of them may be persisted in; care being taken to keep the bowels freely open, and to guard against local fulness or determination of blood. — The diet, regimen, and the management of convalescence, require no remarks beyond those which have already been made (§ 402—405.).

426. *c. Demonomania*, in its different forms, and especially *theomania*, or various states of religious insanity (§ 121.[f] *et seq.*), require a somewhat similar plan of treatment, and the same indications of cure, as have been recommended for melancholia, with which they are more or less closely allied. Moral treatment is particularly necessary; but, equally with the physical, should be varied according to the peculiar features of individual cases. In all the modifications of religious insanity, the consolations of religion, administered by sincere, moderate, and rational ministers of it, are of the greatest service. I have witnessed this in several cases; and, when judicious moral and religious management is aided by a sound physical treatment, recovery will take place in the great majority of instances. In no form of insanity is greater care requisite than in this, to protect the unfortunate patient, and his near relatives, or members of his family, from his insane impulses to commit suicide or murder. PINEL states, that a person, after listening to an alarming sermon, considered himself as irretrievably lost, and murdered all his children, in order that they might not experience eternal damnation. ESQUIROL mentions the case of a woman, who entertained a similar idea, and attempted the lives of her children to preserve them from punishment in a future world; and numerous other instances of the same kind might be adduced. When persons thus disordered succeed in their horrible design, they rarely recover; for no sooner is reason restored, than the distress experienced by them, when reflecting upon the act they have committed, occasions a return of the malady.

427. The physical disorder, both antecedent to, and coëtaneous with, the mental disorder, should be carefully investigated; and particular attention devoted to the states of the brain, of the digestive organs, and of the uterine functions; and determination of blood to the head prevented by local depletions, the shower bath, or douche; by derivatives, and aperients. In the more robust and young, the preparations of antimony, in small doses, and occasionally in larger quantity so as to produce vomiting, are often of service.

428. In those cases, where the patient entertains the belief that he is changed into some animal, — or that he has changed his sex, — or that he has lost a portion of his body, — or that he carries about with him a living thing, or some strange substance in his abdomen, — or that some singular matter is substituted for one of his organs or members, and acts from this impression, — the success of treatment is often not great. In many of these, there is reason to suspect physical disorder, if not structural disease, in the organ or part to which the insane delusion is referred; and to that organ the investigation and the treatment should be especially directed.

429. *B.* TREATMENT of GENERAL INSANITY. — *a.* OF MANIA. — In treating mania, it is necessary to have a most intimate regard to the stage of the disease, — to the degree of general and cerebral vascular action, and vascular fulness, — and to the state of the secretions and excretions. The means which will prove most beneficial during the acute stage, and especially in the early part of it, will be inappropriate, or even injurious, in the chronic period, of the malady. — The treatment of mania is both *hygeienic* and *pharmaceutical.* The former comprises various moral, intellectual, and physical means: the latter, the internal remedies intended to subdue morbid action, and to restore the healthy functions. — *a.* At the commencement, and during the early or *acute stage*, of the malady, the patient should be placed in a large, darkened, and well-ventilated apartment, the air of which should be fresh and cool. Unless his violence is extreme, he ought to be allowed the full range of that, or even of an adjoining apartment, in the watchful care of sufficient attendants; and the restraint even of the strait waistcoat should be dispensed with, unless urgently required. Complete *seclusion* is most necessary, and it should be preferably conducted, in a large institution, conformably with what has already been advanced on this subject (§ 391.). All means of irritation or excitement should be prevented, as far as may be compatible with safety to the patient and those around him. The visits of relatives, connections, or even of acquaintances, should be prevented; and the patient ought to be exposed to the smallest possible number of impressions and causes of excitement. The diet should be rigidly antiphlogistic; and cooling diaphoretics, refrigerants, and diluents prescribed. The nitrate of potash,

the muriate of ammonia, the solution of the acetate of ammonia, the spirits of nitric æther, the solution of tartarised antimony, camphor julep, &c., may be severally used as refrigerant diaphoretics, or administered in the patient's usual drink; or any of the articles prescribed in the *Appendix* (F. 588. *et seq.*) may be employed with this intention.

430. In this form of insanity, patients ought neither to be retained in their own houses, nor confined to their beds. If they are turbulent, vociferous, and violent, their extravagance should be allowed to exhaust itself, without being perpetuated by the excitement of contradiction, irritating coercion, or violence — unless in as far as coercion is indispensable; and, as soon as it shall have served its purpose, it should be relaxed. Soothing means, with firmness, and decision when circumstances require it, should always be tried, and never departed from, even when the utmost restraint is also imposed. The perceptions of the maniac are seldom so entirely obscured as to render him incapable of understanding kind and soothing treatment, or to make him altogether insensible of considerate modes of having recourse to coercion. This has been proved by the able management of cases of this malady in the County Asylum, by Dr. CONOLLY. M. ESQUIROL also observed that coercive means should not be resorted to until the maniac risks his own life, or the lives of others; and even then they should be temporary, and be laid aside as soon as a calm takes place. When the patient will not pass the night in bed, it is better to leave him unrestrained than to coerce him, if he evince no mischievous tendency. This writer has found that the more that liberty has been granted to maniacs, without compromising their safety, the fewer have been the instances of furious mania, and the more rare the instances of the supervention of apoplexy and paralysis, — complications not infrequently produced by the irritation and excitement caused or perpetuated by unnecessary or prolonged restraint, or by restraint imposed in a harsh unfeeling manner. — The *moral treatment* should be conducted conformably with the principles which will be stated hereafter.

431. The *diet* may be more liberal as the disease passes from the acute to the more chronic stage; but in all periods, hunger or thirst, if not appeased, augment the irritation and violence of the patient. The food should be of the most digestible, and least exciting, kind. In some cases, at the commencement of the attack, all food is refused; but this repugnance wears off in a few days. Coercion, in such instances, is unnecessary, as the dislike arises either from gastric disorder, or from excessive cerebral excitement; and, in both circumstances, abstinence is a necessary part of the treatment. At a more advanced period, the farinaceous and leguminous articles of diet, warm milk with bread, rice and milk, ripe and seasonable fruits, and the white meats, are the most appropriate. The *drink* should always be cooling, and febrifuge, as already advised (§ 429.).

432. *β.* The *strictly medical treatment* requires the calmest consideration: the spirit of system, and an irrational method of routine, should be altogether banished; the means of cure should be appropriate to the peculiarities of each case at the time of prescribing for it. The exact pathological or physical conditions should be ascertained as correctly as possible, and remedies prescribed accordingly; and with due reference to the age, habit of body, temperament, modes of living, and occupations of the patient, — to the predisposing and exciting causes, — to the season, — and to the stage and previous character of the disease. — At the commencement of the attack, and if gastric disorder is manifest, one, or even two, *emetics* of tartarised antimony, dissolved in barley water, or in any other diluent, should be exhibited; but if there exist general plethora, as well as inordinate vascular action in the head, a full *bloodletting* should precede the emetic. After the operation of this latter, increased action should be moderated by the continued exhibition of the solution of antimony with liquor ammoniæ acetatis. It is sometimes requisite to repeat the bloodletting, — especially if redness of the face or eyes, noises in the ears, a pulsating pain in the temples, or increased heat of the scalp, or augmented action of the carotids, still continue. When the first bloodletting has been copious, a local depletion may be sufficient, — as *cupping* behind the ears, or in the nape; or the application of *leeches* to the temples, or around the base of the head, or even to the anus. Great care is requisite not to bleed too much; for if maniacs be too much reduced by sanguineous depletions, they are apt to lapse into dementia or imbecility.

433. After the operation of the emetic, a full dose of *calomel*, either alone, or with *James's powder*, may be given, and its operation promoted by some active *purgative* taken a few hours afterwards, — and preferably, according to my experience, by half an ounce, or six drachms, each of castor oil and spirits of turpentine, in any suitable vehicle. If the action of these be tardy or insufficient, it may be promoted by the same or other active cathartics prescribed in enemata. If the cerebral excitement continue after these, or return, the *warm* or *tepid bath*, or a bath of an intermediate temperature, may be used, — the patient remaining in it for a considerable time; *cold lotions* being applied to the head, or cold water being affused upon it. The bath may be resorted to, in this manner, every time that the delirium becomes violent. The bowels should be kept freely open during the attack; and the cooling *diaphoretics* already noticed, with *diuretics*, should be taken every four or five hours, — particularly the solutions of the acetate of ammonia and of tartarised antimony with the spirits of nitric æther. The patient's head ought to be kept cool, by the usual means; and, if the heat be at any time considerable, the *ice-cap*, or the *cold affusion*, may be used.

434. When the violence of the symptoms is abated, the patient may be allowed more liberty, and permitted to enjoy the open air, where he may give vent to his excitement, which will the sooner pass off by being unrestrained. The *diet*, which was heretofore extremely restricted, may be more liberal; and, if intervals of reason occur, the utmost kindness and interest should be manifested for the patient; the *moral treatment* coming in aid of the *physical* and *medical* during the whole course of the malady. If critical evacuations are manifested, they should be promoted by a more nutritious regimen, by gentle tonics, or by means appropriate to the crisis that may appear.

435. The treatment is no longer rational, if all the periods and all the modifications of the disease are treated in the same manner. If mania have occurred after the suppression of an accustomed sanguineous discharge, early bloodletting, and subsequently *local depletions*, repeated at intervals, and in situations having reference to the accustomed evacuation, are indispensable. If it have appeared after delivery, or upon the suppression of the lochia, or of the milk, *purgatives, blisters, derivatives* and *revulsants, setons*, or *issues*, &c. are necessary. If it have followed some acute disease, upon too rapid growth, or on masturbation, the warm bath, with cold applications to the head; a nutritious and *milk diet;* the use of *asses' milk, tonics, cinchona*, or *quinine*, with acids; the cold *shower bath*, or *salt water bathing*, — will be most useful. But in all cases, — and especially when the mental disorder has supervened upon the disappearance of some cutaneous eruption, or of gout or rheumatism, — aperients, purgatives, blisters applied to the nape and kept open, or setons there, or other permanent irritants of the skin, will be found of service.

436. When mania appears in persons of a highly nervous temperament, it is generally independent of vascular fulness, or sometimes is even owing to a deficiency of blood, a larger proportion being determined to the brain than to the rest of the body. In this case, the *cold affusion* on the head, while the lower part of the body is immersed in a warm bath, or the *shower bath*, the patient standing in a pan of warm water, is generally beneficial. If the disease be attended by irritation of the reproductive organs, *tepid baths, cold enemata*, and the internal use of the *acetate of lead* with *hyoscyamus*, or of *ipecacuanha* with *opiates*, or *camphor* with *vinegar*, will be of service. In most cases characterised by nervous symptoms chiefly, the infusion and other preparations of *valerian*, small doses of camphor or of assafœtida, and *prussic acid* or *laurel water*, will be of use, when cautiously administered. In these especially, the cold *douche*, or affusion on the head, has both a physical and a moral effect in calming the patient.

437. If the disease resist these means rationally and appropriately employed, other remedies, of a more perturbating or empirical kind, may be tried; but these require the utmost caution, and their effects must be carefully watched. In strong, young, plethoric, and well-fed persons, bloodletting, generally or locally, may be repeated. When the propriety of venæsection is doubtful, small and repeated local depletions should be adopted, and those which may have a derivative effect ought to be preferred, — as four, five, or six leeches applied to the anus, and repeated every ten or fourteen days, according to the strength of the patient. The *semicupium*, cold applications to the head, and *purgatives* with colocynth or aloes, will also be required; and if these occasion an hæmorrhoidal affection, the circumstance may have a favourable influence on the mental disorder.

438. *Drastic purgatives* are often of service, and particularly in the more obstinate states of mania. They frequently bring away brown, greenish, tenacious, and otherwise morbid secretions, which had been long adhering to the intestinal mucous surface, or lodged in the cells of the colon and in the cæcum; and which had either predisposed to, or perpetuated, the mental disorder. In some instances, a prolonged course of purgatives is required fully to evacuate these accumulations; but, when this is necessary, the patient's strength should be prevented from sinking, by a fuller diet and a more restorative regimen than would otherwise be requisite. It is often difficult to administer these medicines so frequently, or in such quantity, as may be necessary, as maniacs are frequently persuaded that they are given to poison them; but such substances as may be taken in their food, — as calomel, croton oil, elaterium, &c., — may be employed. *Croton oil* may also be rubbed over the abdomen, and cathartic enemata liberally administered. In cases of this kind, the croton oil may be prescribed in small doses, with the extract of colocynth, or the compound camboge pill; and, when the patient has no reluctance to medicine, the compound infusions of gentian and senna, with the sulphate of potash and some purgative and carminative tincture; or a draught containing equal parts of castor oil and spirits of turpentine, may be preferred. If the purgatives occasion any increase of irritation, or are sluggish in their action, the warm or tepid bath will be found of great service.

439. When the integuments of the head appear engorged with blood, — and when, in the advanced course of the disease, or in its chronic state, the head or scalp seems congested, — small and repeated *cuppings*, behind the ears, or on the shaved scalp of the occiput, will often be serviceable; or *free incisions* may be made in this latter situation, as advised by Dr. Prichard, and kept open by lint, or by peas, in the manner of a common issue. In chronic cases, *moxas* and the *actual cautery*, applied to the occiput and to the nape, have been recommended by many Continental physicians; but the other measures just named, or setons or issues in these situations, are equally efficacious.

440. The propriety of exhibiting *opium* in mania has been much doubted. But, when sanguineous depletions have been duly prescribed, and morbid accumulations in the bowels freely and entirely evacuated, — if the scalp be neither remarkably hot, nor congested with blood, and if there be great restlessness, irritability, and want of sleep, — the maniacal excitement being the result rather of nervous disorder, than of vascular action, — the judicious exhibition of opium, or of *morphia*, — especially in conjunction with other appropriate medicines, — will often be productive of the greatest benefit. The opium, or the morphia, however, should be given in a full or very large dose; and, according to the peculiarities of the case, it may be conjoined with *camphor*, or *digitalis*, or *James's powder*, or *ipecacuanha*, or calomel, or with an alkaline carbonate, or with aromatics. There can be no doubt of the benefit which camphor may produce in this state of mania, although this also has been disputed. Those who possess weak powers of discrimination, whose knowledge of morbid actions, and of the operation of remedies, is deficient or limited, will frequently fail in obtaining the usual advantages from medicines, and will hence parade their scepticism as a mask for their ignorance; but *camphor* is a valuable remedy in the circumstances of the

disease now under consideration, — yet it requires caution; and, when conjoined with nitre, and given in small doses, in the more doubtful cases, or where heat of the scalp is still present, — or when prescribed with hyoscyamus, opium, or digitalis, or with vinegar, and in larger doses, in the chronic states, and after evacuations have been energetically employed, and exhaustion is about to supervene, — it generally is productive of the greatest benefit. If the premature or inappropriate use of it should increase the restlessness, or heat of the scalp, cold applications to the head, and diluents with vinegar internally, will soon remove all disorder, or even develope its good effects. — *Vinegar* was much praised by ARETÆUS, LOCHER, and others, in this malady; but CHIARUGGI advised it to be given with camphor. One drachm of the latter may be dissolved in about two ounces of distilled vinegar, and from an eighth to a fourth part of the solution may be taken in any suitable vehicle, every four, five, six, or eight hours. — *Digitalis* has been recommended by Dr. LOCHER of Vienna, and by several British physicians, in this and similar states of mania; and when exhibited in full, or even large doses, it sometimes is of great service: but its effects require most careful watching, — especially when employed in the way most likely to prove beneficial. — The *surprise bath*, or sudden immersion in the sea, or in a cold bath, as advised by VAN HELMONT and others, as well as the *rotatory machine* of DARWIN, although recommended by some writers, are dangerous and highly empirical modes of treatment, which are now justly abandoned.

441. *γ*. When mania assumes an *intermittent form*, the same principles of treatment as have now been advocated should be followed during each attack; and, when an intermission takes place, means should be used to prevent the accession of a paroxysm. — *Cinchona* and *sulphate of quinia* have been employed with this latter intention. Where vascular fulness and increased action, generally and locally, have been removed, and morbid secretions and fæcal accumulations have been entirely evacuated from the biliary organs and intestinal canal, the sulphate of quinine, conjoined with camphor, and with as much of the purified extract of aloes as will promote a free action of the bowels, and occasionally also with hyoscyamus, will prove useful during the intervals, if neither heat of scalp, headach, nor want of sleep, follow the use of it. My opportunities of resorting to this combination of means, in this particular state of disorder, have been few; but I have found the following of service: —

No. 270. ℞ Quinæ Disulphatis, Camphoræ rasæ et subactæ, āā ʒss.; Extr. Aloës purif. ʒss. ad ℈ ijss.; Extr. Hyoscyami ʒj.; Syrupi Simp. q. s. M. Fiant, secundum artem, Pilulæ L., quarum capiat duas vel tres, bis terve in die.

442. When the patient has become calm, and begins to recognise his position and state, although some delusion or delirious excitement may remain or recur, or the moral affections may not be altogether restored, it will generally be proper to remove him from the place to which he had been confined, and to surround him with novel objects, by which he may be amused, or his mind more agreeably engaged, and where he may enjoy the advantages of air and exercise. In this stage of the disorder, a more nourishing and strengthening diet and regimen may be permitted. But, at all periods, the strictest attention should be paid to the secretions and excretions, as well as to calm the mental irritation, and to diminish the number of impressions and causes of excitement by which this irritation is perpetuated.

443. *δ*. *The convalescence* of maniacs is often prolonged and difficult; sometimes it is rapid. Some patients, when restored to their friends, to society, and to their natural habits, do not recover a complete state of health until many months have elapsed. These, especially, manifest great susceptibility and sensibility: they are readily vexed or irritated, are ashamed of their former condition, and often entertain fears at meeting with former friends. Some entertain a dislike, or a hostile feeling, to friends or persons who interested themselves in their behalf during their illness. Where this is evinced, the probability of a relapse, or of an attack of melancholia, or of an attempt at suicide, is great. Convalescents are generally very greatly benefited by travelling for some time, or by a sojourn in the country, or in some suitable place, before they are restored to their families, and are brought in intimate communication with their relatives and friends, or with those who were witnesses of their malady.

444. *b*. TREATMENT OF DEMENTIA AND FATUITY. — The various states of dementia and fatuity generally present little hopes of success from either hygeienic, moral, or medical treatment. — *a*. That variety, which M. ESQUIROL has denominated *Acute Dementia* (§ 152.), is, however, very generally remedied by a restorative method of cure, — by walking and *horse exercise*, — by the *shower bath*, followed by frictions of the surface, — by light and nutritious diet, — by *stomachic aperients*, and attention to the secretions and excretions generally, — and by the exhibition of *antispasmodics* and *tonics* — especially valerian, musk, cinchona, ammonia, camphor, sulphate of quinine, &c., combined according to circumstances. The sulphate of quinine, conjoined with camphor, hyoscyamus, and as much aloes as may preserve the bowels gently open, is often of great service in these cases. The preparations of valerian with ammonia are also most useful. When evacuations have been suppressed, or eruptions have disappeared, these should be recalled, or others substituted in their place.

445. *β*. The *chronic* or *confirmed forms of dementia* and *fatuity* (§ 152. *et seq.*) require a *diet* and *regimen* suited to the peculiarities and circumstances of each case, and to the amount of exercise which is allowed, or the patient is capable of taking. In addition to strict attention to the states of the secretions and excretions, the *shower* or *cold bath*, or sea-bathing, followed by frictions of the surface; *blisters* applied behind the ears, or to the nape, and either frequently repeated, or kept open; *setons* or *issues* in the same situation; *moxas* applied to the occiput; *incisions* of the scalp, or the production of pustules on the shaved scalp by means of the *tartarised antimonial ointment*, — are the chief remedial means. In many cases, these should be conjoined with the restorative treatment just advised (§ 444.). In a very few instances, the occurrence of an attack of acute mania has had a critical effect. — In all cases, country air, moderate exercise, and such occupa-

tions as the incoherent, imbecile, or overthrown state of the mental powers will admit of being attempted, will prove of service — at least, as respects the patient's bodily health.

446. *C.* THE TREATMENT OF COMPLICATED INSANITY (§ 162. *et seq.*) is the most hopeless — especially when any of the forms of dementia are associated with *general paralysis.* — *a.* The means which have been just enumerated (§ 445.), are usually required in this complication; and care should be taken to prevent the bowels from becoming too *constipated* on the one hand, or too much *relaxed* on the other. In either case, inflammation, rapidly passing into sphacelation, generally results. In some instances, the removal, by mechanical means, of hardened fæces from the rectum becomes necessary when the constipation has been prolonged. — *Retention of urine* is an equally frequent and dangerous occurrence in the paralytic form of imbecility and incoherency, and requires a frequent recourse to the catheter. — *Incontinence of urine*, or a frequent dribbling, owing to over-distension of the bladder, is also a common symptom. In this latter case especially, care should be taken to keep the patient dry and clean, — as unconscious or involuntary discharges of either the urine or fæces, soon occasion gangrenous sores of the sacrum, or adjoining parts, in this class of patients. Care is also requisite to preserve them from falls, and from injury from fire.

447. *b. The complication of insanity with epilepsy or convulsions* (§ 174.) does not admit of any precise mode of treatment. The means should vary remarkably, or even be opposite, according to the form of the mental disorder, and to the evidence furnished by particular cases of the existence of general or local fulness of blood, or of increased action, or of organic lesion of the brain. When the convulsive paroxysm occurs *in the course of mania or monomania*, or is in any other way associated with either, general or local plethora, or increased vascular action, or even both, is generally present, and requires sanguineous depletions, the cold affusion or douche, derivatives, cathartics, low diet, and permanent revulsants, or counter-irritants. The principles of treatment stated in the article EPILEPSY, and those advised for *mania* (§ 432. *et seq.*), are usually appropriate in these cases: the application of the means to individual instances must depend upon the discrimination and judgment of the physician. When the paroxysm is connected with *demency* or *imbecility*, or *melancholia*, an irregular distribution or congestion of blood, or organic lesion of the brain or of its membranes, or even a deficiency of blood, may exist, and require the internal and external means already recommended for dementia (§ 444.), with many of those prescribed for the cerebral form of EPILEPSY (§ 61. *et seq.*).

448. *c. Apoplectic seizures* occurring in any form of insanity, should be treated according to pathological principles. If they take place early in *mania*, or in its acute state, general or local depletions, or both, and the other means already advised in *apoplexy*, as well as in acute mania, are generally requisite. But, when seizures of this kind, or resembling it, appear in the course of *demency* or *fatuity*, a want of vital power in the brain, with or without local or general deficiency of blood, or inanition, and, in some instances, with some degree of congestion, is most probable, and sanguineous depletions are then injurious; advantage being often derived from restoratives, when these can be administered, from blisters on the scalp, and from enemata containing assafœtida, camphor, &c. — The *coma* or *lethargy*, and the *vertigo*, often associated with incoherency and imbecility, require the same principles of treatment as now advised, in conjunction with the means recommended for dementia and fatuity.

449. *d. The other complications of insanity* (§ 181. *et seq.*) require but little remark. When the associated visceral disease is of such a kind as to perpetuate the mental disorder, — especially when the *digestive* and *reproductive organs* are deranged, — the removal of such disease becomes an important indication of cure requiring instant adoption; but the means which should be adopted for its removal must vary, or even be different, in different cases. No general principle can be stated, that can apply to all. The secretions and excretions, however, should be promoted; and the processes of assimilation and defæcation — of supply and waste — duly regulated, according to the wants of the economy, and the physical exertions of the patient.

450. iii. OF THE REMEDIES USED IN THE TREATMENT OF INSANITY. — My remarks on this head will be as brief as compatible with the due consideration of some points, respecting which the opinions of the most experienced writers on insanity are greatly at variance, and which could not be so appropriately discussed as in this place. And at the same time that I thus consider the different or opposite views entertained as to the efficacy of certain remedies, I shall also notice other medicines, which have been employed in some states of mental disorder, but to which I have, yet, either not sufficiently, or not at all, directed attention.

451. *A. Bleeding.* — *a.* Great difference of opinion exists as to the propriety of *general bloodletting* in insanity. Dr. CULLEN advised it in the early stage, especially where there are fulness and frequency of pulse, and marks of increased impetus in the vessels of the head; but he admitted that, when the disease has subsisted for some time, he has seldom found it of service. Dr. RUSH carried this treatment further than any other writer of eminence; and urged numerous arguments in support of it, some of which are deserving of attention. He advised large bloodlettings, in the standing or sitting posture, early in mania; and, if the patient bore the depletion without syncope, he directed from twenty to forty ounces of blood to be taken. He was of opinion that this evacuation ought to be carried further in madness, than in any other acute disease whatever; and recommended it to be followed by local depletions, by low diet and refrigerant medicines, by cold applied to the head, and by tepid or warm baths. WEBER, BRÜCKMANN, and J. FRANK carried bloodletting nearly as far as Dr. RUSH. Dr. HASLAM is also favourable to a decided recourse to vascular depletion in madness, though he does not advise it nearly to the extent directed by Dr. RUSH and Dr. J. FRANK; and he considers it equally beneficial in melancholia as in mania. He, however, judiciously limits it

to recent cases and plethoric habits, and prefers cupping on the scalp to venæsection; the quantity of blood to be taken, varying from eight to sixteen ounces, and the operation being repeated as circumstances may require.

452. On the other hand, Pinel considered the signs of vascular action in the head, and of determination of blood thither, as very deceptive; and that bleeding, even in maniacal cases, accompanied by symptoms supposed to indicate plethora and determination to the head, tends to retard recovery, and to render it more doubtful, and to cause mania to degenerate into dementia. M. Esquirol coincides with Pinel in believing madness to be sometimes changed for the worse by bleeding. He has seen it increased even after an abundant flow of the catamenia; and has observed melancholia pass into furious mania after venæsection. He, however, approves of moderate bloodletting in plethoric cases, and when some accustomed sanguineous evacuation has been suppressed. Dr. Burrows has stated, that, following example rather than experience, he tried bloodletting for several years; but discovering his error, he became more cautious, and ordered venæsection scarcely in six cases of simple mania or melancholia in as many years; and that, since he changed his practice, more patients have recovered, and the cases have been less tedious and intractable. Nevertheless, Dr. Burrows, as well as others who condemn general bloodletting even in mania or melancholia, is favourable to local bleedings,—which, he believes, can seldom be dispensed with in recent cases. M. Guislain observes, that most of the cases admitted in the institutions for the insane in Belgium, have been treated by bloodletting before their admission; but that, with few exceptions, the disorder has been aggravated by the practice. He, however, admits the propriety of this measure in the circumstances in which I have advised it in the foregoing section. Dr. Seymour states, as the results of his inquiries of Messrs. Beverley and Phillips, the medical attendants in the Asylum on Bethnal Green, which receives about 400 patients, that the number of those admitted with vascular excitement, requiring bloodletting, are very few indeed; and that the lancet is very seldom used in cases of excitement, if there be no evident effect upon the brain from increased arterial action, so as to induce the fear of approaching apoplexy or paralysis. The reason they assign for not resorting to bloodletting, is, that, having done so in several instances, the result was very unfavourable. The patients were reduced from the loss of blood, and the excitement was not abated: the tongue became typhoid, and the patient sank into a state of collapse, and died. Dr. F. Willis also condemns both general and local depletions: and Dr. Prichard states, on the authority of Mr. Hitch, that Dr. Shute has proscribed the use of the lancet, leeches, cupping-glasses, blisters, drastic purgatives, and the practice of shaving the head, at the Gloucester Lunatic Asylum; and yet, that the proportion of recoveries in this hospital is very large, and that no cases of sudden apoplexy or hemiplegia have happened. Before this practice, however, can be correctly estimated in respect of the treatment of insanity generally, the circumstances connected with the cases for which it was employed should be detailed; and it should be remembered, that a very large proportion of cases sent to lunatic asylums has undergone a more or less active treatment before their admission into these institutions.

453. *b. Local bloodlettings* have been more generally adopted in the treatment of insanity, than venæsection; and they admit of less marked difference of opinion as to the propriety of resorting to them, — many of those who object to the latter, adopting the former. Nevertheless, even local depletions require caution, and are most appropriate in recent cases of mania, and of melancholia. The latter form of disorder requires this mode of depletion almost as frequently as mania, although not generally to the same extent. — The situation of local bleeding is often of importance; and I believe that the occiput, or the spaces behind both ears, and the nape of the neck, should be preferred. The circumstances indicating the amount of depletion, and the frequency of its repetition, are the same as those which show the propriety of the practice on its first adoption. The discrimination and judgment of the physician must guide him in these particulars; but the presence or absence of certain symptoms, about to be noticed (§ 460.), will generally guide his decision.

454. *c. As to vascular depletions*, however practised, no general rules can be assigned. Each case of insanity presents a distinct subject of study as to this practice; and a correct judgment can be formed only after taking into consideration a number of circumstances connected with the age, previous health, nutrition, and occupations of the patient; with the causes of the malady, and with the states of vascular action and vital power. Amongst the more recent writers on insanity, M. Foville, M. Esquirol, and Dr. Prichard have formed the most correct views as to the propriety of vascular depletions in this malady. According to my limited experience, however, the first and last of these writers may be considered as somewhat too partial to the practice; whilst M. Esquirol may be viewed as placing rather too little dependence upon it. Estimates formed respecting it, from the results obtained in public institutions, cannot always be depended upon, unless all the circumstances were known connected with the great majority of patients admitted into them — with the particular classes of patients that they commonly receive; for, in some public, or even private, asylums, many patients are admitted, who have not received benefit from vascular depletion, or for whom it has been injudiciously employed; whilst those for whom it has been properly prescribed, as to quantity or repetition, and who have recovered after recourse had been had to it, require not the aid of those institutions. Besides, of the numbers sent to asylums, there are comparatively few cases which are strictly recent, or in which the period of deriving benefit from vascular depletion is not already passed; and it should also be recollected, that by far the greatest number of those who are admitted into public institutions for the insane, have become deranged from those predisposing and exciting causes which exhaust physical as well as mental power, and that they are precisely the class of subjects least able to bear evacuations, or other depressing means of cure.

455. The lesions found in dissections of chronic cases, by MM. **Bayle**, **Calmeil**, **Foville**, and others, show that they are incompatible with the due exercise of an organ so delicate as the brain, and with the healthy manifestation of the mental powers. And, whether mental exertion or emotion disorder the circulation of this organ, and, consecutively, the material fabric, the integrity of which is necessary to the due performance of the mental operations; or whether the circulation, or the structure of the organ, is the first to be affected, and the mind the last to suffer; still such means as reason suggests, and experience has shown, to be most efficacious for quieting excited and disordered vascular action, generally and locally, without materially depressing or exhausting vital power, cannot safely be always, or even generally, dispensed with.

456. M. **Foville** states that, during many years of extensive practice in one of the largest lunatic institutions in France, he has had recourse to evacuations of blood, general or local, abundant or in moderation, rare or frequent, according to the strength of the patient, the state of the pulse, the redness of the eyes, the heat of the head, and the agitation and want of sleep, in the greater number of cases of recent insanity which have been placed under his care. He has preferred general bleeding, where there existed general plethora; but, in opposite circumstances, he has found leeches on the neck, the temples, or behind the ears, or cupping upon the same parts, or on the shaved scalp, to produce decided benefit. He considers local bleeding so very serviceable, as to prescribe it in addition to general bleeding, when the symptoms imperiously demand this latter evacuation; yet he never rests exclusively upon the efficacy of vascular depletion, but has recourse to other means. He adds, that he has had many cases of intermittent madness, the attacks of which had lasted three or four months, or even longer, when left to nature; but that there was not a single attack of a month's duration, since they were treated by bloodletting, and by warm baths with cold applications to the head at the same time; and that the symptoms were often dissipated in five or six days by these means. The experience and views of Dr. **Prichard** as to this point entirely agree with those of M. **Foville**. Indeed, the practice was advocated by him (*Treat. on Dis. of the Nervous System*, ch. i. Lond. 1822.), long before the treatise of M. **Foville** appeared. In estimating, however, the opinions of physicians attached to public institutions for the insane, as to the propriety or extent of vascular depletions, the sphere of their practice should not be altogether unheeded, and especially the circumstance of the patients having been treated previously to their admission, and the duration even of those which have been called recent cases. It is very obvious, that a patient who has been ill only three or four days, but during that time has been very actively treated, will not bear evacuating means on admission into an asylum; whilst another case, that would have been benefited by vascular depletions in the first few days of the malady, may be injured by them after a week or a fortnight had elapsed,—and this, and even other cases of much longer duration, are usually considered as recent. After all that can be advanced on this point, the propriety of prescribing sanguineous depletions, to whatever extent, must depend upon the pathological knowledge and discrimination of the physician; and if he possess not these qualifications in a high degree,—and unless he study and practice his profession as a whole, and as a profound and comprehensive science, and not as a trade or mechanical art, divisible into a number of separate parts, he cannot truly possess them,—he is quite incapable of rationally and judiciously treating insanity, or any other class of maladies.

457. *d*. There are numerous circumstances which should be duly considered before sanguineous depletions are prescribed for insanity. The predisposing and exciting causes, and the various concurring influences, should be ascertained and kept in view; the age, habit of body, constitution, and occupations of the patient, must be taken into account; and the duration of the distemper, and the means which have been already employed, ought to be precisely known. Next, the exact pathological conditions of the patient should be inquired into, and made the principal basis of the indications of the physical and medical treatment. If the patient be young, plethoric, or strong; if the attack has been acute and sudden; if the carotids and temporal arteries pulsate strongly; if the surface, and especially that of the head, be hot; if the face be red, or the conjunctiva injected, and the pupil contracted; if intolerance of light or of noise, want of sleep, spectral appearances, disordered sensation, and much agitation, be present;—the abstraction, from the arm, of twelve, fifteen, or eighteen ounces of blood will generally be productive of benefit, if it be practised within the first few days of the attack. If the good effect be only temporary, cupping upon the nape, or on the occiput, or behind the ears, will generally be requisite, and should be preferred to a repetition of venæsection.

458. The suppression of evacuations and of eruptions indicates, as M. **Esquirol** insists, the propriety of vascular depletion; and this is the case generally; but care should be taken in prescribing it, even in such circumstances, if the foregoing indications of its propriety are not present in some degree or number. The suppression is an important reason for having recourse to bloodletting; but it should not be the only reason by which the physician is guided in the matter. The mode, or situation, of local depletion, in such cases, should have reference to the evacuation which has been suppressed. If the catamenia or the hæmorrhoids have disappeared, previously to the attack, leeches may be applied to the highest parts of the insides of the thighs, or around the anus.—Acute mania most frequently requires vascular depletion; and next, melancholia. For the latter, venæsection is seldom necessary; cupping behind the ears, or on the occiput, or on the nape, being preferable. The practice is sometimes also requisite in some other states of partial insanity, particularly after the disappearance of an accustomed discharge or eruption. Whenever melancholia or any other form of partial insanity is attended by headach, or by a feeling of oppression or of weight in the head, by a full state of the blood-vessels, and by constipation, bloodletting is necessary. In the more doubtful cases, the application of leeches, or cupping, behind the ears, so as to abstract six, eight, or ten ounces of blood;

or even a smaller quantity, in persons of a weak constitution, is generally beneficial. The earlier in the attack that depletion can be resorted to, the more certain and permanent will be the benefit to be derived from it; and even when an attack is threatened or impending, it should be had recourse to, if the circumstances and symptoms indicating the propriety of it (§ 457.) are more or less manifest.

459. *e.* The *repetition* of vascular depletion should be guided by the same indications as point out the propriety of it in the first instance: when these continue or return, local depletion especially may be safely prescribed a second or even third time,—varying, however, the quantity, with existing symptoms, and with the effects produced by the previous evacuation, and with those observed at the time. The absence of redness or flushing of the face, or even pallor of the countenance, may not be a reason against depletion, especially if the other indications of the propriety of it are present.—When bloodletting in any mode is indicated, it should be performed in a standing, or sitting, or reclining position ; and on the first sign of an effect having been produced in the pulse by it, or of faintness, the abstraction of blood should cease.

460. *f.* It is of great importance to attend to all the *circumstances and symptoms indicating the impropriety of vascular depletion* in the treatment of this class of disorders. These are, chiefly — far advanced age, debility, exhaustion of the vital power, and the puerperal states; the operation of those predisposing and exciting causes which depress or exhaust the vital energies, the physical functions, and mental faculties; continued addiction to the vice of masturbation, or to the inordinate use of spirituous liquors, or to narcotics; insufficient nutrition previously to the attack; all indications of weakness and irritability, without power or tone; and all approximations to the state characteristic of delirium tremens, as a pale or collapsed countenance — very quick, tremulous or small, irregular, soft pulse — copious perspirations, — a terrified, fearful, and agitated state of mind —insensibility of external impressions, and tremors of the extremities. Wherever the tongue is tremulous, or the voice weak or tremulous, the hands unsteady, the pulse weak, quick, or open, and readily compressed; — or when the extremities and skin are cold, damp, or clammy; or the sweats profuse, and the tongue is covered with a dark, brown, mucous coating, — however great the maniacal or delirious excitement and agitation may be, — sanguineous depletion will then be injurious. A natural temperature, or coolness of the scalp; weak action of the carotids, and great frequency of the pulse, with swimmings or giddiness on assuming the standing or sitting position, are also strong indications of the impropriety of bloodletting.

461. *B. The abstraction of heat from the head, bathing, &c.* — The hair should be removed from the head in all acute cases; and where there are great heat of the scalp, and vascular excitement, particularly in mania, the head ought to be shaved. —*a.* For young, robust, and maniacal patients, the *shower bath*, twice or thrice a day, — or the *affusion of cold water* on the head,—is of the greatest benefit, and is recommended by CELSUS, RUSH, ESQUIROL, BURROWS, FOVILLE, PRICHARD, and many others. — When hysterical symptoms are associated with insanity, the affusion of cold water on the head is especially beneficial. Both the cold shower bath, and the cold affusion, are sometimes followed by reaction, and consequent excitement and violence, particularly in irritable temperaments. In these cases, a repetition of the treatment, and the continued application of cold to the head, by means of evaporating lotions, or the *ice-cap*, will generally be necessary. M. FOVILLE places a cap on the head containing ice, and keeps the body immersed in a warm bath for two or three hours; and repeats this practice twice or thrice in the day, according to the violence of the symptoms. At first, he found, when resorting to it only once a day, that reaction, with increased agitation, not infrequently supervened; but, on repeating the bath, and keeping the ice constantly applied to the head, the success of the treatment has been much greater. This combination of warm and tepid bathing with cold applications of various kinds to the head was, however, long previously advised by DANIEL and FOLBERG.

462. The foregoing modes of abstracting heat from the head, as well as the application of evaporating lotions, are serviceable chiefly in *recent cases*, where there are much heat of the scalp, and irritability; but they should be discontinued when the temperature is reduced to the natural standard, and repeated as soon as it rises above it. Intense cold applied to the head, in chronic states of insanity, although the patient be noisy and violent, seldom induces sleep or quiescence: it may even become a source of irritation. The temperature of the scalp should be a guide to the practice in all cases. It may be stated as a general rule, that the heads of all insane persons should be kept cool, and the hair closely cut. They should never wear any covering on the head, when within doors. The only exceptions to the rule are furnished by some cases of dementia, or partial insanity, where the low temperature of the head, and weak action of the carotids, indicate insufficent vascular action and tone in the brain: in these cases, the hair may be worn longer than in others. Insane patients should also sleep with their heads more or less raised.

463. *b.* The *tepid douche* or affusion, *tepid shower bath*, or even the *warm douche*, are severally of use, in certain states of mental disorder, especially when there are great restlessness and want of sleep. In melancholia, I have found the tepid shower bath, commencing with the water at 90°, and gradually lowering the temperature to 80°, and ultimately to 60° or 50°, of great benefit. The *warm douche*, or *affusion*, is most appropriate to delicate females, or to persons of great susceptibility and irritability, conjoined with weak action and deficient vital power; and particularly when there is prolonged watchfulness. *Warm* and *tepid bathing* are extremely serviceable in most cases of insanity, when judiciously managed and conjoined with other appropriate means. If there be great vascular action generally, as well as locally, as in recent maniacal cases, tepid bathing will then be appropriate. If the lower extremities are cold, and the general surface is either of the natural temperature, or below it, warm bathing is particularly indicated. If there are chronic eruptions on the skin, a languid circulation, sleeplessness, and irritability, the warm bath continued for a considerable

time, and frequently repeated, is especially beneficial. In many cases, increased heat of the scalp exists in connection with these states of the general surface and extremities; and for these, the addition of mustard or of salt, or both, to the warm water, whilst cold, in some form, is applied to the head, will be of great service, particularly in the more recent cases. The association of cold applications to the head, and of the *warm semicupium* or *pediluvia*, either simple or medicated, is also useful, particularly when there are much restlessness and watchfulness. — *Cold bathing*, especially salt water bathing, is sometimes of service in chronic mania, and in melancholia; but chiefly during convalescence, and when tonics, change of air, and invigorating regimen, are necessary. It has been advised by numerous writers, but it requires a careful consideration of various circumstances connected with each form of insanity, and with individual cases, before it should be carried into practice. — The *bath of surprise*, or suddenly plunging the patient into a cold bath, and keeping him immersed in it for some time, or until incipient asphyxia is produced, although recommended by Baglivi and Boerhaave, is not only an empirical, but also a dangerous practice. It has been said to have cured many, — that is, many have recovered *after* having had recourse to it; a few, probably, almost immediately; but others have experienced attacks of apoplexy, or of epilepsy, or even of palsy, in consequence of it. The cold shower bath is certainly the safest and most generally applicable mode of cold bathing, for any form of mental disorder: the temperature, as well as the quantity of water, being varied according to the circumstances of the case.

464. C. *Emetics* have been recommended by many writers, in this class of disorders, and especially by Monro, Perfect, Selig, Ranöe, J. Frank, Rush, Cox, Esquirol, and Prichard. They are more particularly indicated in melancholia. Dr. Burrows has had recourse to them, chiefly to free the stomach from troublesome ingesta, accumulated phlegm, or morbid bile; and sometimes to give activity to torpid viscera. He has found them useful, also, by interrupting intense abstractions, hallucinations, and capricious resolutions; and when urine has been retained from obstinacy. They are, however, still more beneficial, by emulging the biliary organs, by evacuating mucous sordes from the stomach, and by rousing the organic and assimilating functions. Dr. Cox states, that in every species and degree of maniacal disease, emetics have proved valuable and efficacious; and Dr. Prichard adds, that Dr. Wake, physician to the York Lunatic Asylum, has assured him, that he has found no remedies so frequently efficacious as emetics. Dr. Haslam, however, although he confirms their utility in cases attended by disorder of the stomach, declares that, after the administration of many thousand emetics, to persons who were insane, but otherwise in good health, he never saw any benefit derived from them. The experience of Esquirol, Foville, and Prichard, respecting them, agrees with my own observation: they are precluded by a plethoric habit, and cerebral congestion — at least, until these are removed. They are most likely to be of service in hypochondriacal dejection and melancholia, attended by torpor; and when the secreting functions and vital actions require to be stimulated and roused. They are also, sometimes, useful during states of furious excitement, — producing calmness, and restoration of sleep. Where there is a morbid addiction to intoxicating liquors, or a ravenous appetite, in maniacal cases, tartar emetic added to these liquors, or to the food, so as to produce either nausea or vomiting, is often of service. When there is much determination of blood to the head, and in other circumstances connected with insanity, vomiting is frequently excited by tartar emetic, or even by other substances, with great difficulty. In these cases, the *cold affusion* on the head, soon after the emetic has been taken, will often cause its operation, as well as protect the brain from the ill consequences of its operation. A combination of emetics is also of use, in these respects.

465. *D. Purgatives.* — *a.* The propriety of exhibiting cathartics or purgatives in the treatment of mental disorders is undoubted; but there are various circumstances, complications, and states of these disorders, which contra-indicate their use. There can be no hesitation in prohibiting them, when there is any indication of inflammatory action in the digestive mucous surface. This surface is often inordinately irritated, or even ulcerated in the more chronic states of insanity, and especially in dementia, imbecility, and fatuity; and where such is the case, purgatives are generally injurious. In other circumstances, purgative medicines, judiciously selected, combined, and managed, are amongst the most important means which can be prescribed in mental derangement. The chief difficulties are the selection and combination of them, appropriately to the circumstances of individual cases; and, in the ability of overcoming these difficulties, the science, ability, and success of the physician consist. Dr. Prichard remarks, that "the mildest cathartics are preferable to others in most instances, because their use can be long continued without injury to the structures on which they immediately act;" and that "the neutral salts, infusion of senna, rhubarb, jalap, castor oil, are, in the majority of cases, sufficiently powerful, and may be used daily or frequently, according to circumstances." More active purgatives than these are, however, often necessary in the early and acute stage of insanity, — and especially in melancholia, mania, and some states of partial insanity. In these, particularly, the intestinal and biliary secretions are frequently viscid and morbid; and the cells of the colon and cæcum are loaded with these and other fæcal matters. Hence a continued use of the more attenuating and solvent purgatives, and an occasional, or even frequent, recourse to the more active cathartics, aided by cathartic enemata, are necessary to the obtaining of the effects which these medicines are capable of producing on the mental disorder. Montanus was correct, when he said that half purges tire and molest the body without being of much service; — and hence the partiality of the ancients for the more drastic purgatives, as well as many of the older physicians among the moderns, in the more acute forms of insanity. Willis gave a scruple each of calomel and extract of black hellebore, with six grains of extract of jalap, in melancholia; and, although the quantities may appear great, yet it should be remembered that calomel in this dose will produce a solvent, rather than a purgative, effect, and that much of the virtues of

extracts were dissipated by the mode of preparation in those days.

466. *b.* That the virtues ascribed to *hellebore* by the ancients, in mania and melancholia, were not greatly overrated, may be inferred from the confidence reposed in it down almost to the present time, and still confided in it through Germany. Celsus gave the black hellebore in melancholia, and the white in mania: Aretæus preferred the former, and Mayerne the latter. Both species are employed on the Continent; but the black is more frequently used. Berends, Greding, Hufeland, Ploucquet, &c. prefer it to the other purgatives; and Quarin prescribes it in the form of Bacher's pills (F. 156.). Dr. Burrows, however, states that he has tried the extract of both the black and the white species, and found their operation very uncertain, and their effects, both upon the mental disorder and upon the excretions, in no way different from other purgatives or emetics. The extract of the *Gratiola officinalis* was much praised by Fischer, Lentin, Hufeland, and Schmidtmann; *aloes*, by Aretæus, and many others; and *jalap*, by Rademacher.

467. *c.* In the acute and early stages of the disease, with manifest congestion or determination of blood to the brain, I have preferred full doses of calomel with extract of colocynth and scammony, or with the compound camboge pill, given late at night, and followed in the morning occasionally by about four, five, or six drachms each of castor oil and spirits of turpentine, taken on the surface of milk, or of some aromatic water. If these do not operate copiously, an *enema*, containing about double the quantity of the oils, should be administered in the course of the day. I have found these oils the most efficacious purgatives — particularly as respects their operation on the mental disorder — in the early stages of mania. In some cases, it will be serviceable to trust to the more common purgative pills, with the addition of a little croton oil, to sharpen their action. After a time, the calomel may be omitted; but, during the acute state of disease, purgatives should be continued until the appearances of the tongue and of the evacuations improve. In many cases, — especially those attended by much vascular excitement, — the addition of tartarised antimony, or of ipecacuanha, to the purgative, will greatly promote its operation, and keep down vascular action. When it is desirable to produce both an emetic and a purgative operation, as in several states of mania, a solution of Epsom salts, or of sulphate of soda, to which tartar emetic has been added, may be taken every hour or half hour, until the effect ensues. It may afterwards be continued at longer intervals, so as to act freely on the bowels.

468. *d.* In the more chronic states of insanity, — and especially when there is much irritability or want of power, or when the tongue continues loaded and furred, but moist, — notwithstanding the frequent exhibition of purgatives, topics should be conjoined with them; and the constitutional powers ought to be supported by suitable diet and restorative medicines. In these circumstances, the compound infusions of gentian and of senna, with sulphate of potash, or sulphate of magnesia, or with tartrate of potash, and an aromatic tincture (F. 266.), or the extract of aloes with sulphate of quinine and camphor (§ 441.), will generally prove not only efficacious in their action on the bowels, but also beneficial as respects the mental disorder.

469. *e.* In respect of *purgatives*, as well as of *bleeding*, it may be observed, that, when insanity proceeds from *moral* and *depressing causes*, they are not generally beneficial, unless conjoined with tonics; and that frequent doses of calomel in such circumstances are often injurious. Purgatives, however, of a *stomachic* kind, or a combination of them with *restorative* medicines, is requisite, in order to promote the secretions and excretions.

470. *E. Mercury.*—Mercurials may be employed for mental disorders with three intentions: — 1st, to evacuate biliary and fæcal accumulations; — 2d, to improve the secretions, particularly that of the liver; — and, 3d, to produce a copious flow of saliva. — To fulfil the *first* of these intentions, calomel is extremely useful, — particularly in melancholia and in mania, — but it should be conjoined with, or followed by, other purgatives. To produce the *second* effect, any of the mercurial preparations may be employed, either alone, or with emetic tartar, digitalis, camphor, narcotics, &c. To accomplish the *third* end, calomel, blue pill, or the bichloride of mercury, may be given in any of the foregoing combinations, or alone. Mercury may also be exhibited in such a manner as to produce both a tonic and an alterative effect. With this view, small doses of the bichloride may be given in a tonic tincture or infusion; or small doses of Plummer's or the blue pill may be taken on alternate nights. The employment of mercurials to an extent likely to produce salivation, or with this intention, is of very doubtful propriety; but was recommended with this view by Willis, Rolfinck, Perfect, Smith, and others. Mercurial salivation was much praised by Rush. Dr. Prichard remarks, that it is by no means a general remedy for maniacal diseases; but in cases of torpor, with suppression, or a very scanty state, of any of the secretions, it is frequently advantageous. He adds, that mercury should be used in mild alterative doses, and discontinued as soon as the gums become slightly affected. Dr. Burrows mentions two chronic cases of melancholic insanity, in which the occurrence of salivation produced a cure. In mania, this effect is occasioned by mercury with greater difficulty than in melancholia. This writer states that he, subsequently to these cases, made many attempts to cure insanity by mercurial salivation; and that, although ptyalism was accomplished in several, yet he never succeeded, but in one case, to restore the mental functions; and this, also, was one of melancholia. Several instances of cure effected by salivation have been recorded by authors; still, I believe that mercury, exhibited to the extent necessary to produce this effect, — and especially when it fails of causing it, — is quite as likely to be as injurious as beneficial — to cause partial insanity, melancholia, and mania, to lapse into dementia or imbecility,—particularly in weak, susceptible, and irritable constitutions. We know, from numerous cases (and several have been observed by me), that the injudicious or excessive use of mercurials will sometimes occasion partial and melancholic insanity, — a circumstance which should, in some manner, influence our practice. Unfortunately, we know nothing of the symptoms, or of the modifications, of insanity, which indicate a

probable advantage from mercurial salivation. The most likely conditions are mania or melancholia consequent upon apoplexy, or complicated with hepatic disease. Mercurials, and particularly salivation, are most likely to prove injurious in every form of insanity which has been occasioned by depressing moral, or by exhausting physical, causes, — and especially by prolonged anxiety, or by masturbation. The bichloride of mercury, however, used in minute doses, as an alterative, in conjunction with tonics, is sometimes of service in several forms of mental disorder, and particularly in scrofulous constitutions.

471. *F. Soporifics.— a. Sleep, &c.*—It has been supposed that it is indispensable to procure sleep, — particularly when watchfulness is protracted; and that relief will generally follow it, when obtained. But sleep is not always much required; and is not even generally followed by relief, although it frequently is. In the early, or even incipient, states of mental disorder, topical bleeding, shaving the head, cold applied to the scalp, and purgatives, are the best means of producing repose; and others, especially narcotics, are then generally injurious: but, in more chronic cases, and where there is obvious exhaustion, consequent upon depletion and evacuations; or a state of great susceptibility and irritability, or of vascular inanition, generally, or locally as respects the brain; appropriate means of procuring sleep, and the use of narcotics, in suitable combinations, are most requisite. Various modes of producing a soporific effect, in mental disorders, have been advised, and very often with little attention to the pathological conditions for which they are severally suited. A few of these have been just mentioned; and others, especially refrigeration of the scalp, swinging, gyration, diet, certain positions of the patient's head, narcotics, &c., have been also recommended, with a view to this effect. It is often more beneficial to procure repose by other, and more indirect, means, than by narcotics; but several of these may be more dangerous than the latter, if empirically prescribed, as they too frequently have been.

472. *Swinging* seems to have been used by CELSUS and CÆLIUS AURELIANUS, to procure sleep; and its influence, in a limited form, is shown, by the rocking of a cradle, on children, and by the motion of a boat or vessel, at sea, upon both children and adults. It obviously affects the circulation, especially that of the brain; and, indirectly, both the stomach and the cutaneous circulation. *Horizontal gyration* was advised by DARWIN, and both it and *swinging* were practised by Dr. Cox, in mental disorders. Dr. HALLARAN, also, adopted both these means, in the Cork Lunatic Asylum, and coincided with Dr. Cox as to their utility. They employed two machines, or rather modifications of the rotatory machine: one, in which the patient was kept in a sitting position; the other, in which he was placed horizontally in a bed or crib. The former, or the *erect* machine, is described as seldom failing to produce copious evacuations in the most obstinate cases,—especially if, on increasing its velocity, the motion be suddenly reversed every six or eight minutes, pausing occasionally, and stopping its circulation suddenly. The effects are, an instant discharge of the contents of the stomach, bowels, and bladder, in quick succession. Should the stomach only be acted upon, a purge is recommended immediately afterwards. The *horizontal* modification of this machine, or circular bed, is employed for procuring sleep; the *erect*, for producing evacuations and moral repression. At *La Charité*, in Berlin, machines for both horizontal and perpendicular rotation were employed. VON HIRSCH recommended swinging in a hammock and various other modifications of this method have been advised.

473. Dr. BURROWS remarks, respecting these powerful means of treatment, that clear evacuation of the bowels should precede the use of either; and that they should not be employed early in the disease, until the violence of the attack has subsided; nor in young plethoric persons, nor where there is vascular determination to the head. The motions ought to be commenced gradually, till carried to the degree of velocity desired. When sleep is the object, a slow and continued action of the machine, without affecting the stomach, if possible, is necessary. When its full motion produces great prostration of strength, and lowers remarkably the circulation and animal temperature, advantage has been obtained from it. In the intermitting form of mania, it has sometimes checked the approaching paroxysm; and in the more continued cases, it has broken the catenation of morbid ideas; and the dread of being again placed upon it has often made the patient more manageable and alive to surrounding objects. Dr. PRICHARD states, that Dr. BOMPAS and Dr. DRAKE, of the Lunatic Asylum at York, have assured him that they consider the rotatory machine as a resource of great value in the treatment of madness. Although the opinions of these physicians, as well as of Dr. Cox, Dr. HALLARAN, and some others, are in favour of the use of this machine in the treatment of insanity, yet it requires so much caution, and pathological observation and experience, to avoid the most dangerous consequences * from it, as to deserve the opinion already expressed respecting it (§ 440.).

474. Want of sleep, in some chronic cases of insanity, sometimes arises from inanition, consequent upon too low diet, and the abuse of evacuating and lowering remedies. In these, as well as in those cases of recent mania, occurring in delicate and nervous constitutions, and arising from a deficiency of blood generally, and possibly also locally in regard of the brain, a full diet, and malt liquor or wine in moderation, will prove the most serviceable soporifics. TUKE, BURROWS, and others have remarked, that noisy maniacs, who hardly ever sleep, by a change from a low to a full diet, especially after a full meal before going to bed, with the addition of a moderate quantity of porter, or even with porter alone, have often slept soundly, and ultimately recovered. It has been recommended to procure sleep by causing the patient to sleep with the head low: but this is a dangerous experiment, especially where there is vascular determination to the brain; and in such cases is sure not to succeed. Indeed, sleep in the

---

* Dr. HORN, of Berlin, remarks, that this powerful remedy should never be employed without great caution, and by experienced persons. Dr. BURROWS adds, that, notwithstanding his caution, a fatal accident occurred to one of his patients from its use, and created so great a popular clamour as to oblige him to retire from *La Charité*.

entirely recumbent position is seldom attended by benefit to maniacs. When, therefore, they can be persuaded to sleep in a semi-recumbent posture, it is to be preferred. The sitting position is generally better than the entirely horizontal; but, whatever may be the position, sleep will not afford relief, if the head be not kept cool by sufficiently refrigerating applications. The hop-pillow is sometimes of service, in the more nervous and irritable cases; but it is rarely of use when there is active vascular determination to the brain, — at least, not until this morbid state is removed. When much disorder of the stomach exists, alkalis and other antacids often assist in procuring repose, — especially when presented in conjunction with narcotics, and when the circumstances of the case warrant the use of these latter means. Very gentle friction of the head, prolonged combings of the hair, and gentle friction of the general surface, especially after a tepid or warm bath, have been followed by refreshing repose, in many of the nervous states of mental disorder, or in cases unattended by marked vascular excitement in the brain.

475. *G. Narcotics.* — *a. Opium and its preparations* have been prescribed in mental disorders by Cox, Odier, Brandreth, Chiarugi, Doemling, Riel, and many others; whilst a few writers reprobate the practice. There can be no doubt of opiates being of great service when appropriately employed. They are not generally admissible, and they therefore require great discrimination in prescribing them. — I have already stated the pathological conditions and the previous treatment warranting a recourse to them in mania (§ 440.); and the same remarks apply to the employment of them in melancholia. In this latter affection, however, as well as in the more purely nervous states of mania and monomania, or when these are complicated with hysteria, it is often necessary to conjoin opiates with some restorative or antispasmodic, as camphor, valerian, ammonia, æther, &c. Opiates are less frequently useful in any of the forms of dementia than in these. M. Guislain justly remarks, that in cases of high excitement, strong full pulse, heat of skin, fulness of the vessels of the head, opium is injurious. It is most serviceable in delicate and attenuated persons of feeble constitution, and in those with cold relaxed skin, and frequent, small, weak pulse. If the disease has been of some duration, — if the circulation has been daily losing its force,— if there are only nervous symptoms to combat, — there can be no hesitation in giving opium. I may add, that it is especially indicated when restlessness, or prolonged want of sleep, has continued after sufficient evacuations have been procured; and still more so, if great exhaustion, tremor, cold perspirations, fits of violent delirium, and a very rapid and small pulse, supervene.

476. Still, much of the benefit that may be derived from opium will depend upon the selection of the preparation, the dose, and the mode of combining and of exhibiting it. The *acetate* and *muriate* of *morphia* are not so likely to disorder the head subsequently, as pure opium, or the simple tincture; and Battley's solution, or the black drop, may be preferred to the latter. When, however, opium, or its tincture, is given with aromatics, consequent disorder is more rarely produced by it. Van Swieten, Darwin, Kriebel, Brandreth, Currie, and others, record cases in which remarkably large quantities of opium have been given with advantage. But these are extreme cases, which merely show what may occur, but which should not guide our practice. It will generally be preferable, when the indications for the use of opium are conclusive, to prescribe it in a full dose at once; especially if the chief object be to procure sleep. In this case, from one and a half to three grains may be prescribed; or half a grain of the acetate or the muriate of morphia. If this dose fail, it may be repeated after six or eight hours; or even a somewhat larger dose may be taken. If a third dose produce no good result, it should be laid aside. In some cases, much smaller quantities may be prescribed with advantage, — especially when debility, exhaustion, or inanition of the vascular system, is great; but, in these circumstances, the opiate should be repeated somewhat more frequently, and be combined with aromatics, restoratives, antispasmodics, or tonics, according to circumstances. Dr. Burrows states, that where an anodyne has been required, he has begun with three grains of opium, and repeated one every two or three hours, — never in this way exceeding twelve grains; and that if sleep has not then followed, he has desisted.

477. The *combination* of opiates with other remedies thus becomes a matter of no small importance; and, indeed, much of the benefit opiates afford depends upon this circumstance. Friborg advises them to be prescribed with camphor and nitre; and Perfect, in nearly a similar form. There can be no doubt of the advantage often derivable from this and similar modes of exhibiting them. Where there is much determination of blood to the head, however, the camphor, unless in very small doses, may be injurious. But, if restlessness and watchfulness arise chiefly from exhaustion, inanition, or morbid nervous susceptibility, — if the disorder be chiefly or altogether nervous — be independent of increased vascular action in the brain, — this and similar combinations, and especially those with the preparations of valerian, of æther, of ammonia, assafœtida, musk, various aromatics, &c., will be most advantageous. In more doubtful circumstances, the combination of opium with ipecacuanha, soap, and a little capsicum, has proved beneficial in my practice. When hepatic derangement is present, or when some degree of vascular excitement still remains in the brain, opiates, conjoined with calomel and James's powder, is sometimes of use; but they should, even in this combination, be prescribed with caution and discrimination.

478. The question as to the employment of opium or morphia, in *enemata*, and *endermically*, is altogether subordinate to that respecting the circumstances in which this medicine is indicated. When these circumstances are clearly manifested, the usual mode of exhibition should be tried, at least, at first, — more especially as it admits of the combination of opiates with other remedies. But, when there is great difficulty in administering them by the mouth, or when they fail of affording the desired benefit, although obviously indicated, then the acetate or muriate of morphia may be sprinkled on a blistered surface, from which the cuticle has been removed; or any of the preparations of opium may be prescribed in enemata. Owing, however, to the occasionally rapid absorption of fluids from

the rectum and colon, a much smaller dose of opium should be exhibited in this than in the usual way. From ten to fifteen minims of the tincture may be administered every six hours. I have found the compound tincture of camphor and the syrup of poppies severally of use; from one to two drachms of the former, and from two to four drachms of the latter, being thus employed, but at different times, or in separate cases. When the patient awakens from sleep procured by the use of opiates, in a state of increased excitement, their exhibition should be relinquished.

479. *b. Hyoscyamus* has an advantage over opium, in neither constipating nor stupefying the patient. In order to obtain decided soporific effects from the extract, a dose of from ten to fifteen grains should be given at bedtime, or from a drachm to a drachm and a half of the tincture. It is apt to produce dryness of the mouth and fauces, and heat or irritation in the stomach; but it calms the circulation, and allays nervous susceptibility and irritation. It is very serviceable in cases characterised by morbid sensibility and irritability, and is much praised by Fothergill, Willis, Stoerck, Selig, Meyer, and Hufeland. Dr. Prichard does not consider it to be a remedy of great importance; whilst Dr. Burrows views it in a much more favourable light. The opinion of the latter physician accords more with my own experience. It is often of great service, when prescribed with camphor.

480. *c. Belladonna* has been recommended in mania by Theussinck, Vogel, Buchoz, Ludwig, Remer, Schmalz, and Hufeland. J. Franck advises it in mania complicated with epilepsy; and Müller prefers the powdered root to the extract, and gives it in gradually increased doses, until the pupil becomes dilated. It has been chiefly employed in the forms of extract and tincture in this country, and is favourably mentioned by Dr. Seymour and Dr. Burrows. Dr. Millingen states that he has found belladonna preferable to hyoscyamus or conium; and that the external employment of the extract, according to the endermic method, has been very effectual in reducing excitement, more especially when applied to the epigastric region. In the case of a female, to whom I was very recently called in consultation, and for whom the indications (§ 440. 475.) for narcotics and restoratives were very manifest, the following pills were prescribed with great benefit: —

No. 271. ℞ Extracti Belladonnæ gr. ij.; Camphoræ rasæ gr. xij.; Ammoniæ Carbon. gr. xij.; Pulv. Capsici gr. iij.; Pulv. Acaciæ et Balsami Peruviani q. s. ut fiant Pilulæ viij., quarum capiat duas, sextis horis.

481. *d. Stramonium* has been employed in mental disorders by Allioni, Maret, Stoerck, Remer, Reil, Greding, and Barton, chiefly in the form of extract and tincture. The vinous tincture of the seeds, made by infusing two ounces of the bruised seeds in eight ounces of Spanish wine, and one of alcohol, acording to most of the German Pharmacopœias, has been recommended by Schneider and Hufeland in doses of ten to twenty-five drops, twice or thrice daily. Dr. Burrows states that one grain of the extract of stramonium has procured several hours' sleep in furious mania, when other narcotics, in considerable doses, had not succeeded; but the patients were much more violent when they awoke. This result too frequently follows the use both of stramonium and of belladonna. The effects of these narcotics, when given in considerable doses, should be carefully watched, and distinguished from the more unfavourable symptoms observed in mania. When dryness of the throat, dilatation of the pupils, anxiety, vertigo, convulsive movements of the extremities, &c., appear, as well as when mental excitement is increased by them, the employment of them should no longer be persisted in. — The extract and tincture of *aconite* have been prescribed by Durande and others; but it is a dangerous medicine in most forms of mental disorder. — *Conium* is less useful than hyoscyamus, and hence unnecessary.

482. *H. Sedatives.* — *a. Digitalis* has been praised as a remedy in mental disorders by Darwin, Ferriar, Currie, Fonzago, Jones, Müller, Guislain, Uwins, Burrows, Ellis, and others. Dr. Cox ranks it next to emetics; and thinks that its efficacy is attributable as much to the nausea it creates, when given in sufficient doses, as to its power over the circulation. Dr. Hallaran considers that, when it is given after the system is reduced by proper evacuations, and particularly by repeated purges of calomel, it is more to be trusted to than any other remedy. Besides its capability of restraining the heart's action, he supposes it to possess remarkable anodyne and soporific qualities in maniacal cases. He commences its use in doses of five or ten drops of the saturated tincture, thrice daily, and gradually increases the dose to fifty drops. Dr. Burrows remarks, that the propriety of lowering the system, by depletions and purgatives, before the exhibition of digitalis is begun, is confirmed by his own experience; and that he perfectly concurs with Dr. Hallaran in considering this medicine as having a very powerful influence in all the stages of insanity accompanied with great vascular excitement and a rapid pulse. Dr. Prichard observes, that the cases in which digitalis is most likely to be useful, are those attended by great arterial action, and high mental excitement. M. Foville considers that it is chiefly beneficial in those cases in which the mental affection is complicated with hypertrophy of the heart. I may remark, respecting this substance, that, when the large doses advised by Dr. Hallaran are given, the well-known effects of it should be carefully watched; and, as soon as they begin to appear, camphor, ammonia, æther, &c. should be had recourse to, and its use relinquished. Digitalis is useful, also, in other forms of the malady besides those particularised above, — and even in the low states of derangement, — when conjoined with camphor, ammonia, and other remedies. In these, as well as in other forms of the disorder, I have given it with great advantage in the following manner, after evacuations had been freely procured: —

No. 272. ℞ Camphoræ rasæ gr. iij.—v.; Pulv. Digitalis gr. ij.; Extr. Hyoscyami gr. vij.; Mucilag. Acaciæ q. s. M. Fiant Pilulæ iij., horâ somni sumendæ.

No. 273. ℞ Camphoræ rasæ gr. ij.; tere cum Mucilag. Acaciæ ʒj.; Aquæ Menthæ virid. ℥j.; Spirit. Ætheris Sulph. Comp. ʒj.; Tinct. Digitalis ♏ x.—xx.; Tinct. Hyoscyami ʒss. M. Fiat Haustus, bis terve in die sumendus. — Vel,

No. 274. ℞ Tinct. Digitalis ♏ x.—xx.; Tinct. Hyoscyami ʒss.; Spirit. Ammon. Arom. ʒss.; Liq. Ammoniæ Acetatis ʒij.; Mist. Camphoræ ℥j.; Syrupi Aurantii ʒss. M. Fiat Haustus, ter in die sumendus.

483. *b. Prussic acid and laurel water* have

been recommended as sedatives in various forms of insanity. The latter was advised by Thilenius; the former, by Dr. Seymour and Dr. Balmanno. Dr. Burrows states, that he made trial of prussic acid, but never derived permanent benefit from it in any one case.

484. *c. Tartar emetic,* in small and frequently repeated doses, in order to reduce vascular excitement in the brain, as well as in the system generally, was recommended by Willich, Müller, Bodel, Frize, Burserius, and Baldinger. A combination of it with tartrate of potass, so as to act also upon the bowels, was advised by Pideret, Fordyce, and Hufeland. Several writers have prescribed it so as to produce more or less continued nausea. Drs. Cox and De Vos, of Berlin, consider it of great service when vascular action is excited, and when the hæmorrhoidal or menstrual discharges have been suppressed, or the portal circulation obstructed. These are, indeed, the circumstances especially requiring it, whether existing in mania or monomania, and more especially in the sanguine or bilious temperament. Where there is more obvious vascular inanition or exhaustion, and in nervous and susceptible persons, a continued use of tartar emetic is injurious. The indications for, as well as against, this medicine, are nearly the same as those which relate to vascular depletions.

485. *d. Cold water,* drunk in large quantity, has been praised by Lorry, Theden, Hilscher, and Hufeland, in melancholia and mania. I have seen it beneficial in melancholia complicated with hysteria. Avenbrugger advised it in those cases especially which are attended by a desire to commit suicide. Falret and Guislain, however, observed no benefit accrue from it in such circumstances. It is probable that, in the very few cases in which it has proved useful, it has acted chiefly as a sedative of irritation in the digestive mucous surface and collatitious viscera, that has excited or perpetuated disorder of the cerebral functions. The remarkably large quantities of water taken almost hourly in most of these cases, may likewise have tended to remove obstructions from some one of the abdominal organs. — Cold water acidulated with the *vegetable acids,* and more especially with *vinegar,* was recommended by Buchoz, Theden, Locher, Selig, and Bang, as a sedative and refrigerant of the vascular system; and in order further to promote this intention, small doses of *camphor,* or of *camphorated vinegar,* were advised by Bona, Perfect, and others. — *Nitre* was also similarly employed, either alone, or with small doses of camphor, so as to secure the refrigerant and sedative effects of the latter. Cold water, medicated in either of these modes, and in the latter more particularly, or by the addition of the *spirits of nitric æther,* is more likely to be of service than when used simply. *Muriate of ammonia,* however, is preferable to nitre, in most cases, — inasmuch as it combines a tonic influence with its refrigerant and sedative properties. — *Acetate of lead* was likewise used by Schrœder as a sedative and refrigerant in mental disorders attended by vascular excitement; but no notice has been taken of it in such circumstances by recent writers. In conjunction with vinegar and narcotics, it is as likely to be of service in these disorders, as in several others in which it has been lately employed. — The *biborate of soda,* and *boracic acid,* were also formerly employed in order to allay vascular action in connection with mental excitement. They have long fallen into disuse; but I have had reason to consider them as still deserving of notice.

486. *I. Stimulants* and *Antispasmodics* are especially indicated in nervous temperaments and delicate constitutions, or whenever the mental disorder appears in connection with deficient nervous or vital power, — when the head is cool, and the mental affection is independent of vascular fulness or action, — when sanguineous depletions and alvine evacuations have been carried sufficiently far, — or when exhaustion follows either these, or the previous excitement. In other circumstances, particularly if the scalp continue warmer than natural, or the carotids pulsate somewhat more strongly, these may still prove of service, if refrigerants be applied to the head; or they may be conjoined, in such circumstances, with sedative and diaphoretic medicines. Of stimulants and antispasmodics, the most frequently useful are, *camphor, valerian, ammonia, assafœtida, æther,* and *the compound spirit of æther.* Others have been employed, as the *oxides of bismuth* and *zinc, castor, serpentaria, arnica, electricity,* and *galvanism.*

487. *a. Camphor,* in the circumstances just specified (§ 486.), is a valuable remedy, and as such has been recognised by Wherlhof, Loebenstein, Kinneir, Fischer, Remer, Avenbrugger, Perfect, Percival, and Hufeland. On the other hand, Haslam, Prichard, and Burrows esteem it of little value. Its influence in this, as well as in other diseases, is very different, according to the doses and combinations in which it is exhibited. Many years since, I entered upon a series of experiments, in order to ascertain its operation in different conditions of the system; and in a paper published some time afterwards (*Lond. Med. Repository,* for Sept. 1825, p. 245.), I stated the result of my researches, and of my experience of it in some cases of mania, which I had seen with Mr. Alcock, Mr. Carroll, and others. Since then I have prescribed it in several cases, both of mania and melancholia, and, generally, with more or less benefit. Dr. Millingen, in a work just published, forms a juster estimation of it than many other recent writers. He states it to be a valuable medicine, but requiring much discrimination. It is not advisable, he adds, when there is cerebral excitement, with a hot dry skin, full pulse, and wild countenance; but where there are much restlessness and uneasinesss, with a low weak pulse, or cold and clammy skin, it will be found most beneficial. This is altogether in accordance with what I have stated respecting it, in the paper just referred to. I have there shown, that camphor in very small doses is refrigerant; but in full or large doses it is restorative, exciting the brain and nervous system, and consecutively calming and anodyne. In mental disorders, it should not be employed until alvine evacuations, and sanguineous depletions, where these are required, have been duly employed. The combinations in which I have most frequently prescribed it, are with opium, morphia, or hyoscyamus, or belladonna, or with nitre, or with the solution of the acetate of ammonia, or with digitalis, or with James's powder, or other antimonials, or with the alkaline carbonates, or with acetic acid, or with any two of these that may

be congruous with the circumstances of the case. Selig, Schoenheider, and Perfect prescribed camphor with vinegar, and Friborg, with nitre and opium, in maniacal cases. The dose of camphor in mental disorders, as well as the combination and mode of exhibiting it, ought to be regulated by the peculiarities of the case, and the effects of the previous treatment. M. Esquirol usually directs from half a drachm to a drachm to be dissolved in two ounces of vinegar, or dilute acetic acid, and given in an aromatic infusion in the course of the twenty-four hours. I have found this mode very serviceable in puerperal and hysterical mania,— other appropriate means being also employed,—but smaller doses are more appropriate in many cases. Cold applications to the head, the shower bath, or tepid bath, &c. may also be resorted to during its use, or when increased heat of the scalp or skin is caused by it.

488. *b.* The *infusion* and *compound tincture of valerian* have proved, in some cases of mania and of monomania, or melancholia, in which I have employed them, of great service — more especially in the states of these disorders already described (§ 486.). When these affections are associated with hysterical symptoms, or when the patient entertains the idea of committing suicide, or has a disposition to indulge or to adopt any dangerous caprice, these preparations are often beneficial,—particularly after appropriate evacuations, and in combination with the solution of acetate of ammonia, or with the alkaline carbonates, or with digitalis, hyoscyamus, &c. — *Musk* has been advised in similar circumstances by Thilenius, Locher, Selig, Pargeter, and Gmelin; but it, and *castor, ammonia, assafœtida,* the *oxides* of *bismuth* and *zinc,* and the *æthers,* are severally inferior to either camphor or valerian: yet they are often useful, especially as adjuncts to other stimulants and restoratives, or to narcotics or sedatives, or even to tonics, in the more strictly nervous forms of insanity, and in cases of debility and exhaustion.

489. *K. Tonics* were recommended by Sydenham, Selig, and Wintringham; and are obviously required in most of the circumstances in which stimulants and antispasmodics are indicated, and particularly in cases manifesting more or less of vascular inanition. — *a. Cinchona* or the *sulphate of quinine* — the latter especially — is often preferable to other tonics, more particularly in the intermittent forms of insanity. The infusion of bark with the solution of the acetate of ammonia is most suitable when vasaular or nervous excitement is passing into exhaustion, or in cases where the propriety of having recourse to tonics may seem doubtful. In circumstances of obvious exhaustion, or inanition; in the more purely nervous states of disorder; in advanced stages, after evacuations have been carried sufficiently far, or when the head is cool, and the pulsations of the carotid are not increased in strength or fulness; the sulphate of quinine, either alone, or with camphor, and with the extract of aloes if the bowels require to be kept freely open, will often be of service. I have given the following pills, varied with circumstances, in several cases of partial and general mental disorder; — the first, when the bowels are costive; the second, when they are too relaxed. In this latter state, a combination of cinchona and opium was recommended by Ferriar.

No. 275. ℞ Quinæ Disulphatis ʒss.; Camphoræ rasæ ℈ij.; Extr. Aloës purif. ʒss.—℈ij.; Extr. Hyoscyami ʒjss.; Balsami Peruviani q. s. M. Fiant Pilulæ L., quarum capiat tres, bis terve in die.—Vel,

No. 276. ℞ Quinæ Disulphatis ℈j.; Camphoræ ʒss.; Extr. Humuli ʒjss. (vel Pilulæ Saponis cum Opio ʒj.); Syrupi Simp. q. s. M. Fiant Pilulæ xxxvj., quarum capiat duas, vel tres, bis in die.

490. *b.* The *arsenical solution* has been prescribed by Neumann, Winckler, Ackermann, and Seymour; and, in states and circumstances of the disease for which I have advised the sulphate of quinine, — and especially in the intermittent forms of insanity, — is well calculated to be of service. It requires not only great discrimination in entering upon the use of it, but also caution as to the quantity prescribed, and the continuance of a course of it; as excess in either may be followed by inflammatory irritation of the digestive mucous surface — especially in the large intestines; or by endocarditis.

491. *c.* The *nitrate of silver* has been recommended by Agricola and Kesler; and, in circumstances truly indicating the propriety of tonics, and when insanity has been occasioned by depressing or exhausting causes, and in purely nervous cases, it may prove of service. It has been considered as more particularly suited to the complications of mental disorders with epilepsy. When, however, this association is dependent upon vascular or structural disease of the encephalon, little or no benefit can result from it. I prescribed it lately in one case of this kind; but was obliged to discontinue it. I have, however, found it of service in two cases of melancholia, with chronic irritation of the digestive mucous surface.

492. *d.* The *infusion* and *tincture of hop* have been recommended by Dr. Mayo; and, in the numerous circumstances and cases of the disease requiring both tonic and anodyne remedies, they are appropriate, and likely to prove serviceable. They, moreover, admit of various useful combinations with other remedies in mental disorders.— The *preparations of iron,* and chalybeate mineral waters, have been employed by Lange and others. They are beneficial in several states of mental disorder, — and especially in the more purely nervous cases, and in states of vascular inanition, — or when derangement has proceeded chiefly from masturbation, or exhausting discharges. — The *sulphate of copper* has been prescribed by Boerhaave and Currie. It is suitable chiefly in diarrhœa occurring in chronic mania, and dementia. — *Absinthium* was used by Aretæus and Paulus Ægineta; and the *muriate of baryta,* by Hufeland.

493. *e.* Various other *stimulants and tonics* have been recommended by writers on mental affections; but very few of these require particular notice.—*Phosphorus* is mentioned by Loebel and Kamer. Its powerfully stimulant qualities require great caution in its use. Formulæ for exhibiting it are to be found in the *Appendix* (F. 6. 7. 428.).—The extract of *nux vomica* is noticed by Murray and others: it also requires great discrimination in employing it (see F. 541, 542.). Both these substances are suitable only in the more nervous forms of mental disorder, — especially in melancholia, and dementia, proceeding from exhausting and depressing causes; and in the circumstances indicating the adoption of the more energetic stimulants, and of chalybeates. In dementia and chronic mania complicated with

general palsy (§ 167.), these medicines may be tried, upon the principle adopted by Celsus — "*Melius est anceps remedium, quam nullum.*"— The *chelidonium* was prescribed by Müller, on account of its stimulant, laxative, and diuretic properties. As it promotes the secreting and excreting functions, and thereby exerts a deobstruent and alterative influence, it may be tried in mental disorders complicated with obstructions or other diseases of the abdominal viscera, — and especially in melancholia. — The decoction of *hypericum* was praised by Meyer and others. It is nervine and stimulant, and is most appropriate in the more purely nervous states of mental affection, and in melancholia, after sufficient alvine evacuations. Dr. Mayo observes, that the use of restoratives and tonics in the first stage of insanity is valuable in the nervous and serous states, but mischievous in the bilious and sanguine; and that, in the stage of exhaustion, they are required in every temperament.

494. *L. External Irritants* and *Derivatives* have been long and generally recommended in the treatment of mental affections. They may be divided into — 1st, *Irritants applied to the scalp*; and, 2d, *Irritants applied to parts more or less remote from the head*, so as to produce some degree of revulsion or derivation from the seat of morbid action. — *a. Scarifications of the scalp* were advised by Aretæus, Cælius Aurelianus, Walther, and Prichard; but they are admissible only when the scalp and head are more or less congested, or when inflammatory irritation or structural change is inferred to exist in the encephalon. In nervous and susceptible persons, and in states of general or local inanition of the vascular system, they may prove injurious. The application of the *actual cautery* to the occiput, or of *moxas* in the same situation, as advised by Pascal, Larrey, and Valentine; and artificial *ulceration* of, or *setons* or *issues* inserted in, the scalp, as prescribed by Horn and others; are indicated and contra-indicated by the pathological conditions just mentioned. Inunction of the tartarised antimonial ointment on the shaved scalp, until a copious eruption of pustules is produced, was advised by Monro, Autenrieth, Jenner, Gumprecht, and others; and has been found of service in some cases of mania, — especially when the acute stage is beginning to decline, or to pass into the chronic state. — The application of *blisters to the head* was recommended by Thilenius, Dürr, and Hufeland. The practice is not without hazard, particularly in the more acute states of mental disorder. It is more appriate in the more chronic and low forms of derangement, and especially in imbecility and dementia.

495. *b.* The application of irritants so as to produce a *derivative* or *revulsive effect* is appropriate in many of the more acute and early, as well as in the more chronic, states of mental disorder; and yet, in very irritable, nervous, and susceptible patients, in the early stage of mania, and in cases where the vascular system is rather deficient, than too full, of blood, these irritants often increase disorder, by exciting the general sensibility. Where, however, the disorder has been consequent upon the suppression of accustomed eruptions, ulcerations, and discharges; and in many cases of melancholia, or of other forms of monomania; derivatives and revulsants are often of much service. In the more acute and recent cases, and especially of mania, they should not be resorted to until vascular depletions and other evacuations have been employed.

496. Various *modes* of producing derivation of disorder from the brain have been recommended. Several of these are already noticed, as also falling under other heads, — especially purgatives, warm bathing, &c. — *Blisters* on the nape of the neck, or on the legs, &c., are often resorted to; but they are seldom of service in mania, — especially in the early stages. They are useful chiefly in the states of disorder just mentioned. Guislain recommends them to the nape, back, or insides of the thighs or legs, when insanity commences with depression of mind or melancholia, and in some states of dementia; but he has rarely found them serviceable in this latter state. Avenbrugger applies them to the region of the spleen, in melancholia; and, when prescribed either to the epigastrium or to the hypochondria, they are sometimes of service in that affection. More advantage may be expected from *issues* and *setons* than from blisters, unless the latter be kept open for a considerable time. Zacutus Lusitanus advised setons or issues to be inserted over the region of the liver or spleen in melancholia. In the majority of cases, however, their insertion in the nape of the neck is preferable, — especially in the other forms of insanity. — *Dry cupping* in this situation is often of service. Dr. Burrows suggests the application of the cups as a derivative to the shaved scalp itself; and, doubtless, this place will often be preferable. I have, in some instances, caused the nurse or attendant to resort to dry cupping on the nape several times in the day, and to employ merely a large glass, tumbler, or any other convenient article, for this purpose, and a piece of lighted paper.

497. The production of *irritation*, or *artificial eruptions* on parts of the body still more distant from the brain, or on the surface generally, has been advised, in order to remove irritation from this organ. They are commonly produced by the *tartarised antimonial ointment*, and by *frictions* with *croton oil*. Thilenius, Odier, Muzell, and Bartholomew recommend *inoculation of the itch*. Besides these, warm mustard *pediluvia*, *mustard poultices* applied to distant parts, and particularly to the lower extremities, the hot *turpentine embrocation* in situations remote from the brain, and *irritating* or *cathartic enemata*, may severally be employed, in circumstances which seem to require them, — and especially when a tendency to coma or lethargy is observed.

498. *c.* Of the various *modes* of external irritation, Dr. Burrows and Dr. Müller consider *pustulation* by means of the tartarised antimonial ointment or plaster, the best; and they prefer the application of it to the shaved scalp. Dr. Millingen prescribes it to the back of the neck. The choice of situation should depend upon the form and stage of disorder. In dementia, in cases attended by stupor or impaired sensibility, and when melancholia or mental depression is threatening to pass into excitement, the scalp may be preferred, after due evacuations have been procured. In some states of mania or monomania, this ointment or plaster may be applied to other

parts. M. GUISLAIN states that he has derived little advantage from it in dementia; but that he has sometimes found it of service in melancholia and in mania. Dr. JENNER published several instances of its success, when applied to the epigastric region, nape of the neck, scalp, and other situations. During the eruption thus produced, a restorative treatment is often necessary.

499. The insertion of *setons* in the neck is considered by Dr. PRICHARD to be most advisable in mental disorders of a chronic form; but he also recommends *issues* made by a long incision in the scalp, over the sagittal suture, where there is great intensity of disease, and a state of the brain threatening a fatal increase. In cases of stupor, and of dementia following apoplexy or palsy, or severe fevers, he believes this method more beneficial than any other. He also suggests a recourse to it in the complication of insanity with general palsy.—M. ESQUIROL remarks, that *dry cuppings*, blisters, and irritating applications are most successful in cases consequent upon metastasis, in monomania attended by stupor, and in dementia uncomplicated with convulsions or paralysis. There can be no doubt of *counter-irritation* being more appropriate in cases characterised by torpor and insensibility, instead of morbid activity or excitement and intensity of feeling. Dr. PRICHARD observes, that, in almost every case of paralysis, with a tendency to coma and lethargy, in which he has used this class of remedies, he has witnessed decided advantage from them. The opinions of Dr. N. HILL, M. GUISLAIN, and of Dr. MAYO, are also in favour of these means.

500. iii. MORAL TREATMENT. — Recourse to moral management has either been too much neglected, or too exclusively adopted. It is but seldom that the truly philosophic physician is satisfied, even in the present day, that physical treatment is duly associated with moral management; or that either, or both, are appropriately directed to the removal of existing pathological conditions, and of the associated mental disturbance. Yet both physical and moral means should be judiciously conjoined and directed to the peculiar circumstances of each case. — It is impossible, especially in my confined limits, to describe the impressions which should be produced, and feelings excited, in order to combat the various states of mental disorder that come before the physician. These means, to be appropriate and beneficial, must necessarily vary in each instance, and be so entirely based upon the ever varying phases of disorder, as not to admit of description. Yet much useful information on this subject, and even the principles of moral management, will be found in the writings of Sir H. HALFORD, Dr. MAYO, Dr. PRICHARD, Dr. BURROWS, MM. GUISLAIN and ESQUIROL.

501. *a*. It is chiefly at the commencement of mental disorder, and when the stage of excitement is about to lapse into comparative calm, that moral treatment is most beneficial. Still it should not be neglected at any period, as long as the patient retains any power of comprehension. Dr. MAYO observes, that, supposing the morbid state to be commencing, every effort must be made to strengthen the influence of the will. The patient, at this period, gradually surrenders himself — though not without a struggle — to some prevailing idea, fear, or delusion: he supposes his friends to be conspiring against him, or insulting or watching him; or he believes calamities of various kinds impending over him. Meanwhile he is struggling against the morbid impression. His efforts, therefore, whether manifest or not, must be aided when right, and his mind tranquillised. His fears should be shown to be unfounded, and his hopes excited and encouraged. To administer this aid is generally a matter of difficulty. The danger of mischief to himself or others, as well as the occasional necessity of repression, dictates *surveillance* (which is always irksome and distasteful), when it is most requisite to conciliate regard.

502. In this state of commencing or impending insanity, the morbid sensations or perceptions, and the unreal ideas or assertions of the patient, should not be rudely contradicted, and imputed to imagination. They are *real to him*; and to controvert them, is the readiest way to irritate the mind, to destroy all his confidence in the judgment and friendship of his adviser, and to strengthen and confirm the disease. His mind requires to be soothed, diverted, and abstracted from the fears and anxieties, by which it is absorbed, depressed, and exhausted. He should be told, that his feelings and perceptions will soon change, as his health improves: he should be comforted by admitting the justness of his complaints, and cheered by attributing them to a temporary disorder of his general health, which will be removed by suitable remedies; and these remedies ought always to be resorted to, in order, both that such disorder, which is never absent, may be cured, and that his confidence may be gained. At the same time, that such admissions are made, and that the utmost kindness and encouragement are evinced, the greatest firmness must be exercised: nothing should be yielded, that ought not to be conceded. He will thus be brought to look for support, and to trust to it, against his own instability and weakness of purpose, as well as for aid in his struggles against morbid impulses and desires. In this incipient stage of mental disorder, much consequent mischief may be prevented by judicious moral management,— by moral and religious consolations, mental abstraction, and diversion; by firmness, kindness, and moral control; by change of occupation, of scene, and of air; by travelling or voyaging; and by the amusements and intellectual *agrémens* of society. Foreign travel is generally preferred in these cases, as affording greater novelty; and visiting watering places, and mineral springs, in connection with travelling, presents several advantages. These conspire, with other circumstances, to excite, or to preserve hope, at the same time that they may be beneficially directed to the removal of physical disorder. At this period, nervous power is depressed by the continued operation of debilitating fears and sensations, whilst the assimilating, secreting, and excreting functions are impaired; and, hence, recourse to chalybeate, sulphureous, or saline waters, or to various combinations of these, in conjunction with moral influences, is frequently of the greatest benefit, — especially in the hypochondriacal and melancholic states of disorder. In addition to these, regular *exercise* in the open air, — particularly walking and riding, — and, still more, exercise and occupations which interest the

thoughts and engage the feelings in an agreeable manner,— as tennis, cricket, fishing, shooting, hunting, gardening, farming, &c.—should be enjoyed, with due precautions against injurious physical agents. The patient should almost altogether live in the open air; but the air should be dry and temperate, and the situation elevated. In unfavourable weather, in-door exercise and occupations should not be neglected. Amusements, also, may be often permitted, especially billiards, chess, backgammon, &c.

503. *b.* Even in the more *violent mental explosions* observed in mania, or when intense *reaction* follows upon depression or melancholia, moral restraint and discipline is often of great service. The union of firmness with kindness, even in such circumstances, is not to be laid aside. As M. Pinel observes, the physician sustains, in these cases, the sentiment of his dignity, and the principles of a pure and enlightened philanthropy. He allows the maniacs all the liberty compatible with the safety of themselves and of others; conceals from them the means of constraint, which he is obliged to employ; and, treating them with indulgence, leads them to suppose that they are only submitting to the laws of necessity. M. Georget remarks, that active and incessant inspection must be exercised, particularly in an asylum, over both patients and attendants. Lunatics evincing a disposition to suicide, should never be a moment out of sight. It is often necessary to confine violent patients, and those who are addicted to indecent practices, with the strait waistcoat. The only measures of punishment, he adds, that should be practised, are the strait waistcoat, seclusion in a cell, the shower bath, and some occasional privations. Dr. Prichard justly observes, that all means of punishment and intimidation should be used as sparingly as possible, and be of the most harmless kind. Solitary confinement, and the strait waistcoat, are sufficient in ordinary cases. M. Foville has recourse to the cold shower bath, and to cold affusion on the head; the violent maniac being seized by a number of attendants, and subjected to the affusion until he becomes subdued. The circular swing has been used with a similar intention; and after it has been once used, a threat of its repetition is frequently sufficient; but the cold affusion is a safer remedy. When obstinate lunatics refuse to take food or medicine, persuasion should be first tried; and if it fail, threats and harmless punishments may be adopted. The stomach-pump may be had recourse to in these cases; the use of it on one occasion will generally prevent the necessity of again employing it.

504. M. Guislain justly remarks, that the physician ought, as much as possible, to abstain from saying or doing any thing before a lunatic, calculated to inspire fear or dread, or by which he might become an object of aversion, or lose the confidence of the patient. Some other person should appear to be the agent in all restraints or punishments that may be required; and the physician should be regarded as the protector of his patients, and the dispenser of kindnesses and indulgences.

505. *c.* When the *acute stage*, or the period of excitement, has passed, a calm usually follows; and, in this state of comparative composure, the morbid delusions adhere to the mind less pertinaciously. The patient himself often begins to doubt their reality; and his estranged affections seem disposed to return. The observations of Sir Henry Halford, on the moral treatment of this period, are particularly deserving of attention. "If, at this auspicious moment," observes this able physician and classical writer, "the intercourse of a discreet friend be permitted, it will cheer the patient's heart; while, by kindness and attention, the physician will easily get possession of his returning confidence, and *so* induce him to unbosom himself of the distempered notions which still continue to haunt him. These, although they be founded in palpable error, the physician will not combat, although he will take proper opportunities of hinting his doubts of their reality. He will never deceive his patient, but take pains to prevail upon him, whenever they recur, to refer them to his unbiassed and more practised judgment; and to be guided by that, rather than by his own, in estimating the correctness of such opinions. He will act, as it were, upon a system of education, and will aim thereby at confirming the spirits, and strengthening the mind of the convalescent: and as the discipline employed in youth encourages and enforces the predominance of reason over the passions, so will discreet converse assist in restoring reason to her seat, and in giving her back again her proper sway over wild impulses. He will engage the mind agreeably, by presenting to it new objects, and by recalling former pursuits to their wonted acceptance." "Had the patient, before he was ill," Sir H. Halford continues, "any favourite amusement of a harmless nature?—Was he fond of *music*, for instance?—Music, without exercising the attention severely, has the power, however, to fix it; therefore, with this 'sola voluptas solamenque mali,'—the only gratification, perhaps, of which he is capable at this period of his mental darkness,—he may be indulged immediately." "Or, had the patient, before he became insane, a predilection for any particular studies? —Would he take the counsel of Lord Bacon, and entertain such as fill the mind with splendid and illustrious objects, as histories, fables, and contemplations of nature?—Or, did he prefer mathematics? and can he now be prevailed upon to enter upon a course of such reading?—Plato has called mathematical demonstrations the purgatives of the soul, as being the most proper means to cleanse it from errors, and give it a relish for truth. Certainly, nothing more entirely bars the intrusion of thick-coming fancies, by occupying the whole mind, than mathematical studies."—Sir H. Halford states, that Dr. A—— became deranged, whilst practising physic in the country, and, after a separation from his family for some months, was advised to resume the study of Euclid, having dropped hints of his partiality to it. He did resume it with the happiest effect, and recovered at length so entirely as to commence business in London, and to practise until his death.

506. Experience has shown, that monomaniacs are injured by directing their attention, or by adverting in any way, to their illusions. It is, on the contrary, requisite to engage their minds as much as possible with very different subjects, and with external objects. Still authors have adduced instances of persons having been cured of their delusions by some deception. Thus M. Esquirol states, that a lunatic would not pass his urine, because he supposed that, by doing so, the

world would be subjected to a second deluge. He was at last prevailed upon by being told that the town was on fire, and that he could save it from the flames. But any advantage obtained in this manner, is generally only temporary. During convalescence, powerful impressions on the mind, even in connection with the patient's delusion, may rouse the patient, as if from a dream, and thus dispel the unreal impression. A female patient had taken the most violent dislike to her family; the tidings of the death of a son in a foreign country excited in her a desire to see her surviving children, and recalled all her parental affection, instantly sweeping from her mind her insane antipathies, and restoring her to right feeling and reason.—(*Rep. of Glasg. Asyl. &c.* for 1839.)

507. On this subject Dr. Burrows remarks, that to reason with a lunatic is folly; to oppose or to deny his hallucinations is worse, because it is sure to exasperate: an impression on him can be made only by talking *at*, not *to*, him. He will often notice what is said to others, and apply much of it to his own situation or delusion. To endeavour to convince him, or to break the catenation of his morbid ideas, by trick, fraud, surprise, or terror, is always attended by hazard. The chances are very many that it will not succeed; and, if it fail, the case is thereby rendered more intractable. "The confidence of his patients," Dr. Burrows adds, "is the sure basis of the physician's success. A cheerful, encouraging, and friendly address; kind, but firm manners; to be patient to bear, but cautiously prudent in answering; never making a promise that cannot safely be performed, and, when made, never to break it; to be vigilant and decided; prompt to control when necessary, and willing, but cautious, in removing it when once imposed;—these will always acquire the goodwill and respect of lunatics, and a command over them that will accomplish what force can never attain."

508. Moral management must necessarily vary with the states of the disease. In the more violent state, restraint and medical discipline should be applied until violence subsides. In the more passive states, restraint is never necessary, unless there be a propensity to suicide, or to a solitary vice which is so frequently a cause of, as well as often an attendant upon, the mental disorder. To prevent this latter propensity is extremely difficult; but various means may be had recourse to with advantage,—and these will readily suggest themselves.* Vigilance is necessary in all cases; for the passive may change in a moment to the active or violent state, and mischief may thus be done before it can be prevented.

509. *d. During convalescence* especially, moral treatment requires the greatest judgment and discrimination in all its relations. In this period, the dawnings of reason should be carefully observed and assisted, and every aid afforded to the struggling efforts of nature. The bodily disease is now loosening its hold over the mental powers; and these powers may be now aided in emancipating themselves from the morbid bondage. The suggestions, and occasionally the reasoning, of the physician advanced with kindness and sincerity, and in the soothing language of friendship, in this stage, often assist in removing weakened and decaying delusions. When convalescence approaches with a revival of the affections, the consolations of the physician are often requisite to calm the feelings which thus burst forth, and to guide them in right directions; or his encouragements are necessary to elicit them, and to give them permanency. Dr. Burrows justly remarks, that if, in reasoning with the patient on any remaining delusion, a painful recollection is revived, the subject should be changed, and resumed at another time. If any domestic event have occurred, during the loss of the patient's reason, likely to excite a strong feeling of joy or of grief, it should be withheld until the mind has acquired strength to bear it; and even then caution in communicating it is requisite. One of the most important and delicate tasks, in communicating with a convalescent, as to the past and present, is to preserve a due medium between gratifying and checking his eager importunities for information. Too great a flood of reminiscences, called up by much information, may endanger the mind enfeebled by disease. The recollections of the past affect different minds very differently. With some, the retrospect is a perfect blank; others remember the past as a dream; others recollect all its realities. Some refer to the past with indifference; others advert to it with gratitude to those who contributed to their recovery; others recall it with pain and abhorrence, and avoid all reference to person, place, or circumstance connected with it. Whatever may be the impression on the mind of the patient, it should be carefully noted, and the conversation with him should conform to it.

510. *e. Religious consolation* is frequently of the greatest benefit in the partial and chronic forms of insanity, when judiciously resorted to. It has been, however, supposed by some to be injurious, or of doubtful advantage, because religion is sometimes a cause of the malady. But, as I have shown (§ 293.), it is only mistaken, unsettled, and fanatical views of Christian doctrines that occasion, in some instances, mental disorder; and, even in these cases, as well as in many others, the truths and consolations which true religion affords, may be made most efficacious means of cure, when judiciously placed before the mind of the patient, at a proper season, by the well-educated and sober-minded clergyman, and when the physician finds no circumstance contra-indicating the propriety of having recourse to them. Mr. Tuke very judiciously remarks, that the mild but powerful influence of the precepts of our holy religion, where these have been strongly imbued in early life, become little less than principles of our nature; and their restraining power is frequently felt, even under the delirious excitement of insanity. Before, however, religious consolation or instruction should be attempted, some information should be acquired of every patient's former and present opinions and

---

* Sir W. Ellis recommends a pair of wide canvas sleeves, connected by a broad shoulder-strap, so as to rest easily on the shoulders. They ought to come up well on the shoulders, and to extend about an inch beyond the points of the fingers; the part covering the hand being made of stiff leather, to prevent the hand grasping any thing. They keep the arms hanging easily by the sides of the body. They are fastened at the back by two straps,—one going from one sleeve a little above the elbow, across the loins to a similar position in the other sleeve; a second lower down; and by three similar straps in the front, the latter being secured by buckles. This mode of restraint is less heating, and produces less pressure on the chest, than the common strait waistcoat.

state of mind: and then religion will often be most advantageously brought in aid of physical and moral treatment; and will tend not only to the restoration of the mental powers, but also to the preservation of them subsequently. The minister of religion, in order to be useful, should have free intercourse with the patient; and administer consolation, or remove doubts, rather by private communication, than by more public instruction or preaching. When the latter is attempted in an asylum, a judicious selection ought to be made of the patients, and the discourse should be suited to their states,—to inspire hope and confidence,—carefully avoiding whatever may perplex the mind, or cause fear or alarm.

511. In a recent report of the Glasgow Asylum for Lunatics, it is stated that, in many instances, the personal and private, as well as public, ministrations of the chaplain have carried consolation and comfort to the minds of the patients, particularly those troubled with distressing apprehensions on religious subjects. The sermons delivered in the chapel are described as being adapted, as much as possible, to the peculiar circumstances of the audience; and as being the means of withdrawing their attention, for a time, from their prevailing illusions. Every thing that is conceived to have a tendency to agitate the mind is carefully avoided, and pains taken to present the most soothing and practical views of Divine truth. Two very important advantages are derived to the patients from the institution of public worship,—that of alleviating the malady under which they labour, and that of gratifying and strengthening those pious feelings from which they derive the greatest consolation.

512. *f. Employments and Amusements.*—*Exercise*, by equalising the circulation, by determining it to muscular structures and to the extremities, and by promoting the exhalations and secretions, is of great service in the partial and chronic states of insanity. But it must be varied according to circumstances, and to the previous habits, conditions, and occupations of the patients. Walking and riding in the open air, or long walks in fields and woods, in company with a suitable guardian, during as great a portion of the day as the strength of the patient will permit, are often of great service. All establishments for the insane ought to be provided with the means of affording to their inmates regular exercise and employment in the open air. They should also be constructed with galleries and covered courts, freely admitting the air, where the patients may take exercise in wet weather. Gardening and various agricultural occupations should engage a considerable portion of time, at stated periods of the day. In manufacturing districts, many lunatics may be made to follow, as a means of distracting their minds from their delusions, their several callings. In the *Salpêtrière*, the women are permitted to sell a part of the produce of their industry, and to apply it to the relief of their necessitous families. Females and men of sedentary habits should be engaged, as much as possible, in some regular occupation. In many asylums—especially abroad—the females are occupied in embroidery, in spinning, knitting, sewing, and various fancy works. Most lunatics are disinclined to work; but kind entreaties, or the prospect of procuring the means of extra comforts, will often tempt them to do something. Even in the early stages of dementia, it is not impossible to induce such patients to work at some merely mechanical occupation. Employments, suited to the previous habits and stations of the patients, mitigate the disease, and tend much to promote the recovery of curable cases. Where the taste and previous occupation of the patient leads to study or sedentary pursuits, these should not be indulged for too long a period without relaxation, or to the neglect of proper exercise in the open air. The greatest difficulty is to find employment or amusement for the higher classes of lunatics. They soon tire of the same pursuit. Reading, chess, cards, bagatelle, billiards, and other games, should be diversified with bowls, tennis, gardening, walking, cricket, and various athletic exercises.

513. *Music* has been considered useful by several writers, as a means of abstracting the attention of lunatics from disordered trains of thought. M. GUISLAIN observes, that music is useful with reference—*first*, to those who play upon some instrument; and, *secondly*, to those who listen to it. It should also be viewed both as a means of beneficially exercising the mind, and as a mere amusement. Persons who can use a musical instrument, and those who are fond of music, will sometimes derive advantage from it; but it is doubtful whether or not it will afford any benefit to others. Dr. PRICHARD states, that Dr. Cox considered that some advantage was derived from it as an amusement; but, that it is of little importance in the treatment of insanity, is proved by the circumstance of Dr. BOMPAS, the successor of Dr. Cox in the asylum conducted by him, having discontinued it. M. ESQUIROL remarks, that he has very rarely obtained any advantage from music. It sometimes calms the spirits, but it exerts no curative influence; it may even render maniacs more furious. He, however, admits its beneficial influence during convalescence—particularly of those who have cultivated music, or who are fond of it. In the more lethargic or dull states of madness, in melancholia, and in other forms of partial insanity, it is often of service; whilst it may prove injurious in some cases of mania—more especially those characterised by a tendency to violent excitement. When the patient has been a performer, playing on his instrument is allowable, as innocently employing both mind and body.

514. *g. Visits of friends, and restoration to society.*—Convalescence is often checked, and the disorder reproduced, by the patient's impatience to be freed from all restraint; and the same effect is too often caused by the impatience and distrust of friends. During convalescence, the physician has not only, as Dr. BURROWS observes, to encourage every dawning sign of returning reason, to employ the soothing language of friendship, and to calm the agony which reminiscence often generates, but also to repress impatience, and to contend with and remove the suspicion and want of confidence, which his cautious course usually produces in relations and friends, and which, if not steadily resisted, endanger the approaching recovery of his patient. The chief risks to which convalescence is exposed, are the *premature visits* of friends, and *removal* from the proper sphere of treatment, to an intercourse with relations and society, and with busi-

ness and its various contingent annoyances and distractions, before the action of the brain, and the manifestations of mind, have been sufficiently restored, or the restoration adequately confirmed. The difficulty of determining when friends should be admitted, and when the patient should be restored to society, is generally great; and the evils resulting from a too long seclusion are sometimes not much less than those which might accrue from premature intercourse. The experience and good sense of the physician will enable him to arrive at a just conclusion with reference to particular cases, — for no general rule on this subject can be laid down. When convinced that either measure will be detrimental, resistance should be carried to the utmost; or until importunity, on the part of those who have authority, assumes the form of *command*. "In yielding, contrary to his judgment, the physician should distinctly throw all responsibility on the applicant; otherwise, the consequence, if injurious, will certainly be cast on him." (BURROWS.) I would add, that the commands of the friends, in such circumstances, should be required to be made in writing; as they will be much more cautious than otherwise in thus making them, and as evasions of responsibility will often be attempted, in this as well as in many other matters, when there is no written document to prove its existence.

515. Before permitting the visit of any person, the state of the patient's feelings and views to that person should be ascertained. It will be also preferable to select for the first interview some one who the least interests the patient's affections; and, if this communication is borne without any ill effect, a nearer friend or relative may be selected, leaving the object of warmest attachment to the last. Proceeding in this cautious way, Dr. BURROWS remarks, the too sensitive or feeble mind is gradually brought to bear a renewal of intercourse without being too much moved. But the physician might be deceived by the dissimulation of the patient, who will often assume an appearance of amendment merely to obtain an interview with a friend; his only object in seeking it being to request his release, or to complain of his treatment.

516. Cunning being a characteristic of madness, the physician should always be upon his guard against being imposed upon. Many are fully aware that, if they can conceal their delusions, they may be considered well; and, when only one delusion is entertained, it is often difficult to detect it. Dr. BURROWS had a patient, whose specific delusion gave rise to outrageous conduct requiring her confinement; and yet this delusion was successfully concealed for nine months, — at the end of which time it was manifested in an alarming manner. In this, and similar cases, a recovery might have been prematurely or improperly pronounced. On the other hand, it is possible for an impression, made previously to complete mental derangement, to be so firmly retained after recovery, as to have the semblance of a delusion, and yet be none; especially when no recollection is retained of what has occurred between the accession of disorder and recovery, and when the patient reasons and acts upon this conviction, and reckons a circumstance long passed as having recently taken place. Much discrimination and experience are necessary to determine when seclusion may be terminated, and the patient restored to society. If the disorder have been caused by intemperance, a longer confinement after convalescence is required, than in other circumstances; for the longer it is protracted, the greater is the chance of the patient being induced to relinquish a recurrence to the cause.

517. *h. After the patient is restored to society*, moral and hygeienic management ought to be continued for a considerable period. Due care should be taken not to excite, or inordinately indulge, the passions and desires. Irritations of mind and body should be avoided; and all emotions which depress, equally with those which unduly stimulate the mind, ought to be evaded. Mental exertion is also injurious. The intellectual as well as the moral powers should not have too much imposed upon them. They ought, at first, to be only agreeably and gently exercised; and, as they re-acquire strength, more may be exacted from them. Travelling, agreeable society, change of scene and of air, regular and early hours of sleeping and dining, pleasant occupations, and exercise in the open air, are all of the most essential service after recovery. Of no less importance are regular and abstemious modes of living, and strict attention to the states of the digestive and excreting functions. In a word, the *predisposing* and *exciting causes* ought to be carefully avoided.

518. iv. CLASSIFICATION OF PATIENTS, AND ARRANGEMENT OF INSTITUTIONS, &c. — *A. The classification of the insane*, in both public and private asylums, is too frequently dependent upon their extent, and upon subordinate circumstances and arrangements; instead of these being made subservient to a classification, which may contribute to the safety and speedy recovery of the patients. It is difficult, and even not very requisite, were it easy, to state the classifications and arrangements which may be adopted in various circumstances. In these matters, as well as in the *organisation* and *management of these institutions*, medical knowledge, and an acquaintance with mental disorders, under the guidance of common sense, will generally enable the physician to arrive at judicious conclusions. But in all arrangements and modes of organisation, a due separation of the different classes of cases, and of convalescents, should be secured; and no asylum, public or private, should be allowed or licensed, that is not placed under the constant superintendence of a regularly educated and qualified medical practitioner, who should reside in it, and be in constant communication with its inmates. On this particular topic, much information will be obtained in many of the recent publications referred to in the *Bibliography* attached to this article. I can furnish only a brief abstract of what has been stated regarding it, by PINEL, ESQUIROL, and GEORGET.

519. *a. The classification* of lunatics is requisite, not merely for the purpose of separating such as are liable to injure themselves or others, but also with the view of permitting those to associate together, who may contribute to each other's cure. A lunatic asylum should be composed of several parts, more or less insulated. There ought to be a quarter for each sex; a division for the violent; a second for those who are tranquil; a third for those labouring under accidental disorders or complications; and a fourth for convalescents. It

is, above all, necessary to separate the sexes, the convalescents, and those who have depraved habits, and indecent manners. Divisions should also be allotted for those of melancholy feelings; for those in a state of imbecility or dementia; for the noisy and furious; and for those who are untameable, or are confined by way of punishment. It would be preferable for each division to have a court planted with trees, and a garden for the patients to walk in.

520. *b.* It is further requisite, for the convenience and safety of the patients, and to facilitate vigilant superintendence and protection, that an asylum should be built on level or slightly elevated ground; — that the cells for violent patients should be spacious, with a door and window opposite each other, and opening from without; — that they should be boarded, and not paved; furnished with a bed firmly fixed in the wall; — that all the cells should communicate with covered galleries or corridors, in which the patients may walk in bad weather, and by means of which the inspectors and servants may easily pass to different parts of the building; — that all the rooms should be warmed by pipes conveying hot water in preference to hot air; — that water should be abundantly supplied; — that the privies should be arranged so as to occasion no inconvenience to the patients; — and that there should be places appointed for a general work-room, for a common dining room, for baths, shower baths, and douches. — There should be suitable dormitories for convalescents, melancholic patients, idiots, and those who are debilitated. For others, little cells with one bed are preferable; the patients going out of them in the day-time, and associating with one another, — no companions being allowed in the night.

521. *B. The selection of the inspectors and attendants* in lunatic institutions is of great importance. Insane persons look upon the attendants as accomplices in the power which has deprived them of liberty and as inhuman jailers, view them with suspicion and hatred, and even abuse and strike them. It is often difficult to make servants understand the states of those committed to their care, so as to enable them to preserve their temper, and to act with kindness and firmness in all circumstances; and it is not easy to convince them, that the insane have the use of some of their faculties, and are often quick, observant, and cunning. Those attendants, who have been themselves insane, are generally the most careful, forbearing, and kind to those over whom they are placed. M. Esquirol has a favourable opinion of convalescents as keepers: they are compassionate to the infirmities which they have themselves so recently suffered; they aid the physician more efficiently; and their examples are encouraging to others. The attendants ought always to be sufficiently numerous, — one attendant to from eight to twelve male patients, and one to from ten to fifteen females, according to circumstances. Old military men are amongst the best keepers; for, as Dr. Conolly remarks, they keep up their own authority, and are obedient to superior orders. The physician of a lunatic asylum ought to be careful to instruct those who are to have the management of the patients. It is absolutely requisite, that a judicious arrangement of authority and subordination be established in all asylums, and that the power of the physician should be superior to all, in respect of every thing that concerns the patients.

IX. INSANITY, CONNATE; AND PUERILE IMBECILITY.

— Syn. *Idiotcy, Natural Idiotism, Congenital Privation of Intellect, Puerile Imbecility, Weakness of Mind, Silliness, Stupidity, Connate Fatuity, Primary Fatuity, Idiotism, Mental Deficiency, Original Deficiency of Understanding; Stupiditas, Vecordia, Amentia, Imbecillitas Ingenii; Fatuitas; Amentia Congenita,* Sauvages, Sagar, Vogel; *Démence innée,* Fodéré; *Idiotisme,* Pinel; *Die Spracheigenheit, Blödsinn,* Germ.; *Idiotismo,* Ital.

522. Defin. — *Deficiency, or entire privation, of intellect, appearing during infancy and childhood, depending either upon an original defect, or upon an arrest of the developement of the mental faculties.*

523. *Puerile imbecility and idiotcy* may be considered as representing two grades of primary mental deficiency. The former is that state or degree in which there is an original impairment, but not an entire want, of intellect. The latter is a more complete grade of deficiency, sometimes amounting to an absence not only of the moral and intellectual manifestations, but also of the instincts necessary to self-preservation. Between, however, this, the highest degree of idiotcy, and the slightest state of intellectual deficiency, there is every intermediate grade. Original defect of intellect should not be confounded with the imbecility, or incoherency, or fatuity, consequent upon other forms of insanity, or upon cerebral diseases, — the *Amentia acquisita* of authors; nor with senile fatuity, imbecility, or dotage, — the *Amentia senilis.* The distinction has been very properly made by Esquirol and Prichard; and most succinctly and correctly stated by Dr. Klein Grant, under the article *Amentia,* in his edition of Hooper's *Medical Dictionary.* — Original deficiency and entire want of intellect may appear unconnected with any bodily disease — may be *simple* and *uncomplicated;* or they may be *associated with* other maladies — or *complicated.* Complete idiotcy, especially, may be further associated with congenital deficiency of some organ or part, or connected with malformation, or arrest of developement, of some portion of the brain, or organ of sense.

524. i. Deficiency of Intellect appears in every grade and form until it amounts to complete idiotcy. The slighter degrees of deficiency are manifested chiefly by weakness of character and capacity, or by stupidity or deficiency of the powers of perception, or of the understanding. These grades of defect are generally not sufficient to render an individual incompetent to the management of his affairs, or to conduct himself with propriety; and are hence not considered sufficient to constitute unsoundness of mind, in its legal acceptation. But as the original defect may present every grade, from the slightest of those just mentioned to complete idiotcy, it is difficult to draw any line of demarcation between what may be considered soundness or unsoundness of mind. This line must still remain unfixed, or at best be only conventional, for no standard or criterion can possibly be established. As in consecutive impairment, or disorder, of mind, so in original deficiency of intellect, there are every

shade and degree of mental manifestation, descending, from the highest state of perfection of the human understanding, down to the lowest state of privation of intellect and of instinct; there being no break in the scale, or in the continuity of declension.

525. Deficiency of intellect begins to appear from the *first* to the *eighth* or *ninth* year of age. When it is congenital, it may manifest itself even somewhat earlier than the former period. When it arises from an arrest of the developement of the mental faculties, owing to injury or physical disease, it may not be evinced until a later period than that assigned. In this latter case, the deficiency is seldom so great as when it occurs at earlier stages, or depends upon changes that have taken place in the encephalon either previous to, or soon after, birth.

526. From what has been already stated, it is obvious that all the grades and forms of original imbecility cannot be described within moderate limits. Nor is minute description at all requisite: the works of GEORGET and ESQUIROL will furnish it, and numerous illustrations of it. I may, however, briefly observe, that imbecile persons have a limited capacity for certain actions or employments, and acquire some degree of facility in performing them. These they generally execute in a tolerable manner, whilst they are quite incapable of any other modes of exertion or occupation. Habit has a great influence on all their proceedings, and gives to many of them an appearance of regularity which may be mistaken for the result of steadiness and of higher powers. All are, however, deficient in the powers of attention and thought. They are generally timorous, often docile, weak and inconstant in purpose, and frequently irascible. The senses of some give rise to feeble and dull impressions, — of others, to more lively perceptions. Memory is strong in some; whilst in others it is weak, confined in its range to the most ordinary objects and frequently repeated ideas, or it hardly exists. They display some indications of mind, of intellectual faculties, and of feelings and affections; and they have the use of speech and of language generally in a degree proportionate to the grade of perfection of their several senses and mental powers. They show the same varieties of character, inclination, and moral propensity, as persons of stronger understanding. Left to themselves, they are careless, lazy, and filthy. At the age of puberty, they evince the animal instincts by the most offensive gestures, habits, and solitary vices. Some become subject to paroxysms of capricious violence, to hysteria, to nymphomania, or satyriasis. Many are prone to lying, pilfering, and stealing. Several lapse into melancholia, or sink in a gradual decay of physical health — frequently owing to an uncontrollable addiction to masturbation. In other circumstances, they eat and digest well, and females have the catamenia regularly. Some imbecile persons evince signs of talent in particular pursuits, particularly in music and the ruder of the imitative arts. Others have retentive memories, learn languages, and are capable of other acquirements, while, in all other respects, they are deficient in any talent, and generally in mental power. They commonly present much of the character, in manner and in the developement of mind, of infants or children. They are deficient in affection, in application to any pursuit, in the powers of comprehension, of pursuing a train of ideas, and of entering into a rational or sustained conversation. They are without energy and steadiness, and are fearful and cowardly. They are incapable of reflecting, of contriving any thing, or of accomplishing any thing.

527. ii. IDIOTCY. — *More or less complete privation of the mental faculties.*—This is the highest grade of original deficiency of intellect. In this state, the moral, the reflecting, and the intellectual manifestations are altogether wanting; and sometimes the instinctive emotions of mind are also partially or totally undeveloped. Indeed, the different states of idiotcy depend chiefly upon the extent of deficiency of this class of the mental powers. Those instinctive feelings and desires, which are the most generally bestowed on the animal creation, and which especially subserve the preservation of the individual and of the species (see *Classif.* in note to § 66.), are chiefly present, — frequently in an inordinate degree, — and are deficient only in the most extreme cases. Infants that become idiots have large or ill-formed heads, imperfect features, take the breast with difficulty, are long before their eyes follow the light, and often squint. They are puny, lean, of bad complexion, have a feeble physical developement and vital endowment, are incapable of instruction, cannot learn to walk until they are six or eight years of age, or sometimes till they attain the age of puberty. They articulate imperfectly, or learn but a few words, or are altogether incapable of articulate sounds, although they may possess the sense of hearing. When the head is very small or very large, or flattened in any direction, or much deformed, death generally takes place early, — generally long before puberty, or at any age between this epoch and the first months of existence.

528. *Idiots*, both children and adults, present not only these deformities, but all those described in the article CRANIUM. Their features are irregular and repulsive; their eyes are blinking, and deeply set; their lips are large, thick, flaccid, and relaxed; their mouths are gaping, and admit of a drivelling of the saliva; their organs of sense are imperfect — they see and hear imperfectly, or are entirely deaf and dumb. Their taste and smell are also deficient, and they eat without selection of food. If speech exist at all, it is extremely limited, and drawling or lisping, and capable of expressing only the most urgent physical wants. Their chests are narrow or contracted; their limbs ill-formed; and their gait, as well as all their movements and attempts at muscular exertion, unsteady and awkward. They are sometimes club-footed, and the muscles of the arms or legs contracted. They are commonly rachitic, or scrofulous, — often partially or generally paralytic, or subject to epileptic fits. Not only are they without the reflecting and intellectual faculties, but even their sensibility is deficient; and sensation, when excited, is scarcely followed by perception of objects or ideas. They are incapable of directing their attention to any thing. Owing to the defective state of their instinctive feelings, they appear far below the brutes in the scale of animal existence; and, as M. ESQUIROL remarks, are monsters or imperfect beings, who are destined to a speedy extinction, if the tenderness of parents, or the

compassion of others, did not prolong their existence. Yet idiots have the bodily appetites, and sexual desires, — sometimes in an inordinate degree, and repulsive manner. They often exhibit signs of premature puberty, and are generally addicted to masturbation. They are often, also, subject to anger and rage. Some display faint glimmerings of intelligence, when their notice is excited by strong impressions on their senses. They then appear to look at certain things with a vague expression of pleasure, or of curiosity: they seem to desire some objects, particularly articles of food: they occasionally indicate, by gestures or cries, objects of desire or aversion, or the pleasure or pain which they feel: they come to know the persons who habitually take care of them; but they are incapable of dressing or undressing themselves, or of the common acts of cleanliness. Others are debased to the lowest state of being, — are sometimes even unconscious of their evacuations, and incapable of commanding or restraining them; and enjoy only a vegetative existence, devoid of sensation and sensibility. Idiots of a higher grade of developement are capable of moving from place to place; but are, like machines, made to repeat the same movements: they move their arms, as if to facilitate progression; laugh mechanically; utter inarticulate sounds, as if to amuse themselves; occasionally catch a few notes of a simple tune, which they constantly repeat; and become attached to particular places and positions.

529. iii. The COMPLICATIONS of imbecility and idiotcy are chiefly those already noticed (§ 523. 528.), more particularly rickets, scrofula, general or partial palsy, epilepsy, contractions and malformations of the extremities, deficiencies of the organs of sense, goître, and, still more particularly, CRETINISM, which, in its fully developed states, is always associated with more or less absolute want of the mental powers. (See art. CRETINISM.)

530. iv. The CAUSES of imbecility and idiotcy are of importance, both in a medical and in a social point of view. — *A. The remote causes* are — 1st, Those which are referable to the parents, and which operate previously to birth; — 2dly, Those which more especially belong to the patient, and which affect him subsequently to birth. — *a. The causes which operate previously to birth* are—whatever exhausts or debilitates the parents, or renders the reproductive acts imperfect*, — as habitual debauchery, solitary vices, and drunkenness; sexual debility, or states approaching to impotency; the insalubrity of certain localities, particularly those observed to produce *cretinism* (§ 6.); the scrofulous and rickety diathesis; and the advanced age or debility of one or both parents. ESQUIROL states, that idiotcy is more common in the country — especially in mountainous districts — than in towns. He, as well as numerous other writers, insists upon the influence of violent mental emotions, and moral shocks during the early or middle months of utero-gestation. Several modern writers have affected to doubt this cause; and, as they cannot dispute the frequent occurrence of arrest of developement of the nervous system, and congenital deficiency of mental manifestations, in the children whose mothers had been thus affected during the period of their fœtal existence, yet consider the phenomena in no way connected — as coincidences merely, — and as holding no relation of cause and effect. The vulgar opinion, however, of this matter is nearer the truth; and the evidence of the arrest of developement having been produced by the mental, and the consequent physical, shock of the mother during gestation, is much more conclusive than most of the evidence usually furnished us in physiological and practical researches, or than that upon which we are constantly acting in the discharge of our professional duties. It by no means follows, that the phenomena which we cannot satisfactorily explain, should therefore not exist; or that relations, of which we cannot trace the connection conclusively, are on this account altogether wanting. Yet even here, however difficult may be the explanation, or apparently loose the connection, both the one and the other may be furnished conformably with views stated in this and other articles. It is not improbable even, that the means sometimes used to conceal pregnancy, or to procure abortion, may so affect the developement of the fœtus as to produce idiotcy. The same causes which occasion congenital and chronic DROPSY *of the Brain* (§ 283. *et seq.*), will sometimes cause more or less complete deficiency of the mental faculties. Inflammation, or tubercular disease, of the brain or of its membranes, during fœtal existence, will disturb or arrest the subsequent developement of these parts, and of their respective manifestations. Injuries of the head of the fœtus, sustained during parturition, have also produced this effect.

531. *b. The causes which operate after birth* are, chiefly, injuries of the head; diseases of the brain — particularly acute and chronic hydrocephalus; inflammations of the brain or of its membranes; convulsions; dentition; exanthematous fevers — especially when attended by cerebral affections; tubercular disease, with or without inflammation, of the encephalon; remarkable precocity in connection with a susceptible and irritable state of the constitution; and very early addiction to the vice of masturbation. This last cause is frequently productive of those states of imbecility, or slighter forms of mental deficiency, observed at advanced stages of childhood, or near the approach of puberty. To these causes may be added the use of improper coverings on the heads of infants and children, as ably illustrated by M. FOVILLE (*Deformat. du Crane result. de la Méth. de couvrier la Tête des Enfans.* Paris, 1834.).

532. *B. The pathological causes* are chiefly imperfect, deficient, or interrupted developement of the encephalon, and affecting it either partially or generally; sometimes associated with changes of the consistence and form of the brain, and not infrequently with some of the usual consequences of old or previous inflammation of the membranes — particularly the arachnoid, and of the cerebral structure. MORGAGNI and others found the brain harder than natural. MECKEL says that

---

* A physician was consulted by a gentleman who was anxious to marry, to secure a fortune in his family, but had been some time deterred from marriage by a consciousness of weakened sexual powers, consequent upon masturbation in early life. As he was young, and his constitution had apparently not suffered seriously, he was advised to marry, under the conviction that a moderate exercise of the sexual functions would assist in restoring their energies. The advice was adopted; but the first child that was born was an idiot. The later children were sound: he had gradually recovered his powers.

it is often drier, lighter, and more friable than usual. MALACARNE states, that the convolutions of the brain are numerous in proportion to the intelligence, and that in idiots they are always few. They are very generally smaller, less prominent, and less numerous in these persons, than in others. M. ESQUIROL has observed the lateral ventricles uniformly very small in idiots. In some, one hemisphere is much less developed than the other; and, occasionally, one lobe is more deficient than the rest. In these cases, one or more limbs have been paralysed. — These deficiencies have been more frequently observed in the anterior, than in the other lobes. The cerebral substance is sometimes softened in one part, and hardened in another. For further details, see the articles BRAIN, CRANIUM, and EPILEPSY.

533. v. The TREATMENT of imbecility and idiotcy is rather *preventive* than *curative*. — *Prevention* depends entirely upon the avoidance of the remote causes, and upon the employment of those means which tend to strengthen the physical powers of the parents, and of the offspring after birth. That much is owing to the constitutional powers of the parents, is shown by numerous facts, and by the circumstance of several idiots or imbecile persons being often met with in one family. Attention to the general health of the infant, good nursing, daily cold ablutions, frictions of the surface, a dry and temperate atmosphere, frequent changes of air, and due promotion of the several secretions and excretions, are the chief means by which a healthy developement of the offspring of debilitated persons can be secured. In every case, a strong, healthy, and young wet-nurse should be procured immediately for the infants of such parents. As dentition and childhood approach and advance, the means and the cares advised in the articles AGE and DENTITION are especially required. — The *curative means* are limited to physical and moral education, which may be of use in the slightest forms of imbecility, but which are of no avail in the more manifest states, and in idiotcy.

X. INSANITY, PUERPERAL. — SYN. *Insania Puerperarum, Mania Puerperalis*; *Puerperal Mania.*

534. DEFIN. — *Disorder or aberration of mind, of either a partial or general form, occurring in any period of the puerperal states.*

535. i. DESCRIPTION. — *Puerperal insanity* may appear in a slight or partial, or in a severe and general, form. It most frequently, however, assumes the form of mania, and melancholia. In a few cases it presents a mixed character, or that of melancholia alternating with mania. Insanity may occur — 1st, At any time from conception to parturition — the insanity of pregnancy — *Insania gravidarum*; — 2dly, From parturition to about three weeks or a month subsequently — the insanity of parturition — *Insania post partum*; — 3dly, At any period during lactation, or soon after weaning — the insanity of lactation — *Insania lactantium.* In the *first* of these periods, it is usually slight or partial, chiefly affecting either the moral manifestations or the understanding. In the *second*, it most frequently assumes the form of acute mania,—sometimes passing into a chronic state,—but rarely assuming the character of dementia or fatuity. In the *third*, melancholia, slighter forms of mania, and partial insanity are the most common. — Any of these states of disorder, occurring in any of the *periods* now specified, may be *simple*, or *complicated*, in respect of succession, or co-existence, with some other malady — particularly *hysteric affections, epilepsy, convulsions, catalepsy* and *cataleptic ecstacy, uterine hæmorrhage, disease of the uterus or ovaria.*

536. *A. Insanity during Pregnancy — Insania Gravidarum.* — Pregnancy generally occasions more or less excitement of the nervous and vascular systems; and sometimes gives rise to various morbid impulses or aberrations of mind — especially in females hereditarily predisposed to insanity. The mental disorder may appear immediately upon conception, and disappear on quickening; or it may occur at any period of utero-gestation, continue through, and cease upon, delivery; or it may persist through all the circumstances consequent upon parturition. In this latter case, however, it seldom retains the same form or character, but passes into one more general or severe; melancholia, or any other partial disorder, being aggravated into mania. In some cases, the mental affection commences as hysteria, or in some one or other of its numerous states; and in two cases in which I was consulted, it was preceded by catalepsy and cataleptic ecstacy — affections intimately allied to hysteria.

537. The most frequent states of mental disorder observed in this period are *melancholia*, and the *moral disorders* described above (§ 69. *et seq.*). The singular feelings and desires — the whims and caprices — frequently attending this state, cannot be considered as amounting to insanity, inasmuch as they seldom engross the mind, or withdraw it from all other thoughts and pursuits, or overwhelm the natural feelings, or influence the conduct. As soon, however, as any singular desire exercises such a sway as this, — when it engages the mind and influences the conduct, uncontrolled by natural sentiments and requisite occupations, — it then amounts to moral insanity, and requires both moral and physical treatment. In some females, pregnancy occasions not only irrepressible fears and melancholia, but also various disordered impulses, productive of crime or various unlawful acts, either before the control of reason can be exercised, or in opposition to the feeble efforts of the understanding (§ 92.). In unmarried females, the melancholic feelings, the irrepressible fears, and the morbid impulses of the mind, are often heightened by shame, remorse, the abandonment of the seducer, the consciousness of poverty, or the fears of ill-treatment. Under such affliction, the mind may be so disordered as to perpetrate various crimes, or even suicide. In this state, consciousness may be lost for a time, and acts be committed, before it be restored, of the most flagrant nature, and the most repulsive to the natural disposition and feelings. This is the more likely to occur, if the mental distress be attended by fits of *leipothymia*, or of *fainting*, or by *convulsions*. In some cases, recovery from these attacks, or the restoration of consciousness, is attended by a short period of maniacal excitement, or a state of momentary delirium, during which suicide, murder, or incendiarism, has been perpetrated. In most cases of mental disorder occurring during pregnancy, and

in all that I have seen, there was either an hereditary predisposition to it, or the patient had been previously subject to obstinate hysterical affections, and had experienced overwhelming or intense emotions of the mind.

538. *B. Insanity after Delivery* — *Insania post Partum* — *Paraphrosyne Puerperarum*, SAUVAGES. — *a.* Insanity consequent upon parturition is often preceded, during pregnancy, by harassing fears, and unfavourable presentiments. In some cases, various hysterical affections, preternatural susceptibility, great exuberance or depression of spirits, suspicions, irritability, a state of stupor or sopor, and slight or short attacks of mental aberration, have occurred during gestation. Generally the disease appears from the second or third day to the sixteenth or seventeenth; but it may occur almost immediately after parturition, or be delayed to the third or fourth week. Some writers assign the third and fourth, and the thirteenth, fourteenth, and fifteenth days, as the most frequent periods of its appearance. The chance of an attack, however, progressively diminishes after the third or fourth day. The disorder may commence with want of sleep, inquietude, sadness, anxiety, or ill-grounded fears respecting some matter; the phenomena of mania, or profound melancholia, supervening upon these symptoms. Sometimes an explosion of mania takes place more or less suddenly; but more frequently the patient's manner becomes quick, the temper irritable, and the nights restless, for two or three days before the attack. The form of the mental disorder varies remarkably; but the maniacal states are the most common. Next to these are melancholia, and diversified forms of monomania. During either of these disorders, and in melancholia especially, suicide may be attempted or committed. Mania may alternate with melancholia, and this last with other varieties of partial insanity. At first, and particularly in cases occurring soon after delivery, the disorder is maniacal. Sometimes the patient evinces a childish disposition for harmless mischief; is gay and joyous; laughs, sings, and talks loud and long, occasionally obscenely, and is careless of the infant and of every thing about her. She is often also suspicious; imagines every thing poisoned; and is busy with some idea, illusion, or some fancied object. In other cases, the maniacal excitement is much more intense; and the conversation and conduct more violent. These states may pass into melancholia, but very rarely into dementia or fatuity.

539. *b. The physical symptoms* are referrible chiefly to the digestive organs, and to the nervous system. The *bowels* are torpid, the secretions and excretions impaired and morbid; the stools are unhealthy, and generally very dark and offensive; and, from inattention or obstinacy, sometimes passed without regard to the natural calls. The *tongue* is moist, white, furred, or loaded; and as the disease proceeds, it sometimes becomes brownish, — mucous sordes accumulating on the teeth and lips. There is little or no appetite, and rarely much thirst. The *pulse* is frequent, small, weak, compressible; and sometimes it is but little, or not at all, accelerated, or it becomes less frequent as the disease proceeds. The *skin* is relaxed and moist, particularly about the neck, and generally cool, especially on the extremities. The head is often hot, or is warmer than usual, but the heat is not always permanent; it frequently occurs at intervals, and is sometimes greatest when the rest of the body is cool. Occasionally the scalp is cool throughout. *The general heat* of the body is rarely increased, unless when the disease is coincident with the first secretion of milk, or with inflammation of the breasts, or unless when caused by the violent exertions of the patient. Pain, sense of pressure, or tightness, of the *head*, is often felt, with uneasiness of the scalp, noises in the ears, and sometimes throbbings of the temporal arteries. There is little or no *sleep*. The *face* is generally pale, unless when the maniacal excitement is great, and then it is often flushed or turgid. The eyes are vivid or slightly red; but both they and the face are occasionally pale, although the patient is most violent. The *abdomen* is usually soft, cool, and free from pain on pressure, unless sometimes in the hypogastric and iliac regions. The *breasts* are generally flaccid, and the secretion of milk either impaired or arrested; but the milk, in some instances, is not materially diminished, although it is generally deficient in its healthy and nutritive properties. The *lochia* are often deficient, but they are sometimes abundant or offensive.

540. *c.* The insanity of females recently delivered, commonly assumes the form now described; but its character varies remarkably: in some cases, it nearly resembles *sub-acute phrenitis*, delirium supervening, as in the form of the disorder described by Dr. J. BURNS, in which the symptoms of morbid vascular action in the encephalon precede the mental disorder. In other instances, the insanity verges in its character towards *low nervous fever*: it is then generally preceded by watchfulness, fever, the supine posture, heat of scalp, and injection of the conjunctiva. Images or illusions supervene, the ideas become rapid, and the delirium, passing into a muttering delirium, is soon confirmed. The pulse is quick, and the milk and lochia are usually suspended. Enough has been stated to show that, as regards puerperal insanity, as well as many other maladies, the marked lines of demarcation attempted to be drawn by authors and nosologists do not exist in nature; but that there is a gradual approximation of character observed in this, to other diseases of the nervous system, — that the transition from puerperal insanity to phrenitis on the one hand, and nervous fever on the other, is often manifest; cases occurring in practice of an intermediate nature, and referrible to one malady as much as to another.

541. *C. Insanity during or after Lactation* — *Insania Lactantium* — *Mania Lactea*, SAUVAGES — is generally gradual in its approach; or it is preceded by symptoms premonitory of its occurrence. When, however, violent impressions are made upon the mind, or the secretion of the milk is suddenly disturbed, the disorder may burst forth unexpectedly. Generally, however, a change of temper or disposition is remarked for some time previously. The manner becomes hurried, sleep disturbed, the temper irritable, the countenance suspicious or distrustful, and the patient voluble and negligent of her infant. At length, sleeplessness, incoherence, or violence of language and conduct, and delusions, supervene. Occasionally, various hysterical and cataleptic symptoms are associated with these; and sometimes acts of violence, or attempts at suicide, are perpetrated, even

before the nature of the malady is suspected by her friends. The disease may occur at any period of lactation; but it is more frequent on weaning, or very soon afterwards, than at any other time. The melancholic and monomaniacal forms of insanity are oftener observed during this period, than violent mania: and when the latter occurs, it is apt to pass into melancholia, or to alternate with it. Insanity during this and the preceding periods may present some one or other of the *complications* noticed above (§ 166. *et seq.*).

542. ii. DIAGNOSIS.—The diagnosis of puerperal insanity is sometimes difficult, especially after delivery. Some modern writers have endeavoured to point out differences, rather than to describe the relations, really subsisting between it and other diseases, especially *phrenitis* and low *nervous fever*. But, as I have already stated, the transition of the one into the other, is not infrequent; or, the pathological condition of these maladies are very nearly the same in many cases. The absence of fever has been considered as particularly characteristic of puerperal insanity; but fever accompanies a considerable proportion of cases, especially those commencing about the fourth or fifth day, when the secretion of milk excites, some degree of febrile commotion in the system; and, at a later period, when the lochia disappear. Still it is a rapidity of pulse, and an irregular determination of blood, with increase of heat about the head, rather than fever, that are more commonly observed.

543. *a.* In *phrenitis*, the patient has headach, vertigo, throbbing in the temples, a beating noise in the ears, flushing of the face, injection of the conjunctiva, intolerance of light and of noise, heat of the scalp, rapid pulse, dry skin, suppression or sudden diminution of the milk and of the lochia, constipated bowels, and scanty and high-coloured urine, before delirium appears; and very frequently these symptoms are ushered in with chills or rigors. In proportion as these phenomena are manifested before the mental disorder appears, the disease may be viewed as possessing an inflammatory character. Puerperal phrenitis, moreover, soon passes into stupor, coma, subsultus of the tendons, catchings in the limbs, and unconscious evacuations; and often terminates unfavourably as early as the third, fourth, or fifth day, and rarely passes the eighth; whereas, puerperal mania, even in the most febrile and unfavourable cases, generally is prolonged beyond this period, unless very injudiciously treated. In the former, the physical disease is manifest and developed before the delirium appears, and is evidently the cause of it; in the latter, the mental disorder is coetaneous with, or even previous to, the physical disturbance.

544. *b.* When *low nervous fever* occurs after delivery, or during lactation, it will hardly be confounded with this disorder, as the febrile commotion precedes mental disturbance for several days; muscular power is prostrated, the patient preserving the supine posture, or being incapable of continuing any other; the pupils are but little sensible to light; the tongue is tremulous; the patient is sleepless, and complains of confusion and giddiness, rather than of pain of head; and when delirium supervenes, it is of an incoherent and muttering kind, and very rarely violent, or attended by muscular exertion. The pulse is very quick, and small; the bowels are readily moved; and the lochia or milk is suppressed. As the malady proceeds, coma, startings of the tendons, pickings of the bedclothes, unconscious evacuations, and the usual phenomena of nervous exhaustion terminate life.

545. These maladies the discriminating physician will never confound with true puerperal mania; and he will carefully distinguish such cases as present an intermediate form between either of them, and the latter disorder. He will, moreover, keep in recollection the circumstance of these diseases frequently leaving, as the physical disorder subsides, more or less of mental disturbance behind them, which may assume the form of chronic mania, or melancholia; and the risk of this result will be great in proportion to the evidence of an hereditary predisposition to insanity, and to the nervous or melancholic temperament of the patient.

546. *c. The relation of puerperal insanity to delirium tremens* has not been adverted to by writers, although the connection is obvious in many instances, and of practical importance. I have been called to several cases, which, in their remote causes, and essential features, were instances rather of delirium tremens occurring in the puerperal state, than true puerperal insanity. In some cases, the tremor is hardly to be observed, or is present only for a short time; and yet, the affection presents the other characters of that disorder, and has arisen chiefly from the abuse of intoxicating liquors. Puerperal insanity, attended by tremor, usually appears soon after delivery, and is to be imputed chiefly to the effect produced on the system, already injured by excesses, by the shock of parturition, by the consequent evacuations, and by the abstraction of accustomed stimuli.

547. iii. PROGNOSIS.—Opinions of the result of puerperal insanity were either stated in too favourable terms, or imperfectly ascertained, previously to the appearance of the works of ESQUIROL, HASLAM, BURROWS, and GOOCH. M. ESQUIROL states that, of 92 cases, 53 recovered, and 6 died,—leaving 31, or 1 in 3, as incurable. Of 85 cases, admitted at Bethlem, Dr. HASLAM observed 50 recover, and 35 incurable. Dr. BURROWS mentions 57 cases, of which 37 recovered,—28 within the first six months; 10 died, 1 committed suicide, and 11 remained uncured. Dr. GOOCH observes, that these statements present a prospect unnecessarily gloomy and discouraging; for, of the many patients, about whom he had been consulted, he knows only two, who are now, after many years, disordered in mind,—and of them, one had already been so before her marriage. It should, however, be recollected, that only the more obstinate and severe cases are sent to asylums, and not until medical treatment had been already employed; hence the more unfavourable results furnished by ESQUIROL, HASLAM, and BURROWS. Of those not sent to such institutions, a much greater proportion, than that assigned by these writers, recover, under judicious management, particularly of the non-febrile form of the malady, which is fortunately the most common. Cases attended by much febrile action, more especially those approaching either to the character of phrenitis on the one hand, or to that of nervous fever on the other, are attended by more danger; and frequently either terminate fatally, or in per-

manent insanity, — particularly if an hereditary predisposition to insanity exists. Of the 10 cases which ended in death, out of 57, recorded by Dr. BURROWS, 7 occurred within twelve days, 2 within seven weeks, and 1 after four months. Two had active uterine disease, and 2 others died in consequence of relapses.

548. The *causes* have a considerable influence on the result. Of the cases which I have seen in the Queen's Lying-in Hospital, and to which I have been called in private practice, a much larger proportion of incurable and fatal cases has existed amongst the unmarried, than in the married. Previous distress of mind is sufficient to account for these results. Of the cases of married females, that have occurred in the above Institution, since I became consulting physician to it (1822), two were represented to me by the matrons as having been caused by remorse, consequent upon incestuous intercourse; and both these terminated fatally. It may be inferred, from the results observed by several practitioners, that about four patients in five recover their intellects, and that about one in eight die, generally within the first month of the disease, the greater number within a fortnight. The proportion, however, of unfavourable cases, is manifestly greater than this, in unmarried females. The chief danger in this disease, especially in the more pure, or non-febrile, form of it, arises from debility and exhaustion of nervous power. And this is the more to be dreaded, when the disorder follows hæmorrhage, or improper bleeding, when the pulse is very rapid, weak, or small, or fluttering; and when there are great restlessness, and long-continued want of sleep. Recovery is generally more likely to take place, the more remote the attack from the period of parturition, or when the disorder occurs during lactation. The appearance of the disease during pregnancy should lead the physician to anticipate a severe form of it after delivery. Moral causes, also, give rise to more severe and dangerous attacks, than physical causes; and the maniacal form terminates favourably more frequently, and in a shorter time, than the melancholic, in as far as the recovery of reason is concerned; but deaths are more likely to occur in it, — at least, after a short period from the attack. Of 55 recoveries, M. ESQUIROL states, that 38 took place within the first six months. Of 35 recoveries, recorded by Dr. BURROWS, 28 occurred within the same period. When the delirium is of a gay character, and the patient sings, laughs, talks wildly, and is a little mischievous, it rarely lasts long; but when it is attended by great suspicion, apprehension of poison, and sullenness, or when suicide is meditated or attempted, it then assumes a more serious character, and is not soon cured. Upon the whole, this disorder requires a very cautious and guarded prognosis.

549. iv. CAUSES. — *A.* The *predisposing causes* of puerperal insanity are nearly the same as favour the occurrence of other forms of mental disorder,— the puerperal states being superadded causes of predisposition to these, and the period immediately following delivery being the most influential of these states. Hereditary influence, constitutional debility, and susceptibility of the nervous system, most powerfully co-operate with the puerperal states. Of the 92 cases noticed by ESQUIROL, 16 were attacked from the first to the fourth day; 21, from the fourth to the fifteenth day; 17, from the sixteenth to the sixtieth day; 19, from the sixtieth to the twelfth month of lactation; and 19, after forced or voluntary weaning. Dr. BURROWS remarks, that of the 57 cases which he has observed, the disease commenced on or before the fourteenth day in 33; and after the fourteenth day, and before the twenty-eighth, in 11 instances. — As to the *age* at which the disorder most frequently occurs, he observes, that from the age of twenty to thirty it is more frequent than at any other age, in the proportion of nearly two to one. M. ESQUIROL states, that of 92 females, 22 were from twenty to twenty-five years of age; 41, from twenty-five to thirty; 16, from thirty to thirty-five; 11, from thirty-five to forty; and 2, from forty to forty-three. — The *comparative frequency* of this disease in married and unmarried females has not been duly attended to. Nearly one third of the cases adduced by M. ESQUIROL were those of unmarried women; whilst a fourteenth only of those observed by Dr. BURROWS were unmarried. There can be no doubt, that the disease is, relatively to the number of pregnant single women, much more common in them than in the married. This is to be imputed to the more general and intense operation of the moral exciting causes on the former than on the latter. M. ESQUIROL imputes the frequency of this malady, in the unmarried, in great measure, to the influence of suppression of the lacteal secretion, and premature weaning, — comparatively few unmarried females suckling their children. In this country, however, the majority of them find situations as wet-nurses. Females who have been subject to *hysteria*, particularly its more severe and obstinate forms, previously to pregnancy, are very liable to puerperal mania; and those who have been once attacked, are highly predisposed to the disease on each successive return of the puerperal states. Of the predisposition arising out of hysteria, I have met with several remarkable instances. Some writers have remarked, that nearly one half of the cases, which they have treated, have, more or less, depended upon hereditary predisposition. Of the instances, which I have seen in the lower classes, a large proportion has occurred in those who had been addicted to the inordinate use of spirituous or malt liquors.

550. *B.* The *exciting causes* are also very frequently the same as produce mental disorders in other circumstances; although there are others, which especially belong to the puerperal states, or which produce their effect chiefly in these states. There are some, also, of a physical or pathological kind, consisting of changes in the sexual organs and nervous system, connected with impregnation, parturition, and lactation. The most common exciting causes are, moral emotions, and errors of diet and regimen. Of the latter, improper food, stimulating or heating articles, exposure to cold air or currents of air, damp clothes, the evaporation of liquid perfumes, the suppression of the lochia or of the milk, premature exertion, the use of cold fluids, and neglect of the abdominal secretions and excretions.

551. *Moral emotions* have a remarkable effect upon both the nervous system and the secretions, during the puerperal states — great in proportion to the nearness of their occurrence to the period of delivery. The comparative influence of the

moral causes has been attempted to be estimated by M. ESQUIROL and Dr. BURROWS; but the application of numbers to the estimation of the separate value of individual influences, in the production of disease, especially as diversified combinations of both exciting and predisposing causes generally occasion it, leads rather to erroneous than to correct conclusions; and is, at best, a parade of accuracy, in respect of matters which admit only of approximations to the truth. Besides, the relative influence of particular causes vary with the age, constitution, modes of living, previous health, and occupations of the patient; and with seasons, weather, epidemic states of the air; and with climate, situation, and peculiar circumstances of the country. M. ESQUIROL states, that 46 of 92 cases of puerperal insanity were caused by moral emotions, whilst Dr. BURROWS estimates the physical as being ten times more influential than the moral causes. My observations lead me to infer, that M. ESQUIROL is very much nearer the truth, even allowing hereditary predisposition, which exists in a very large proportion of cases, to be a physical cause.— The most frequent moral emotions are those which have been already noticed (§ 549.) as operating chiefly on the minds of the unmarried; also fright, fear, anxiety, chagrin, anger, domestic dissentions, grief at the desertion of the father, or at the death of the infant; dread of the malady after having experienced an attack, &c. The influence of terror and fear was shown by the cases which came under the care of M. ESQUIROL, in 1814, and 1815. Of 13, which he admitted in the former year, 11 were caused by fear. A sudden shock, or whatever startles or alarms the patient, as a sudden clap of thunder, will often occasion the disease, especially soon after parturition. The abuse of intoxicating liquors exerts both an exciting and a predisposing influence; and it has not only a direct, but also an indirect, effect. These liquors either excite the malady by immediately stimulating the nervous and vascular systems, at periods when susceptibility is augmented and vital power impaired; or, in other cases, they indirectly cause it, by the sudden abstraction of the accustomed excitement they have afforded, at a time when the frame is depressed by the suffering and by the evacuations attending parturition. When puerperal insanity proceeds from this source, it may either assume more or less of the characters of delirium tremens (§ 546.), or vary but little from its usual forms. In order that the treatment should be successful, care ought to be taken to ascertain the existence or non-existence of this cause from the attendants most competent to furnish the information.

552. v. PATHOLOGICAL STATES. — *A. The appearances observed after death,* caused by pure or true puerperal insanity, particularly when it occurs soon after delivery, or during suckling, consist chiefly of deficiency of blood in the brain and its membranes; and, in some instances, of slight effusions of serum between the membranes, and in the ventricles. There are no signs of inflammation, or even of congestion, excepting in such cases as have approached in their characters to phrenitis on the one hand, or to nervous fever on the other; and in these, appearances of an inflammatory or of a congestive nature, with or without effusions of serum, are often observed. The pure cases of the malady present little beside anæmia of the brain and its membranes, and of the system generally. Morbid changes in other parts of the body, or even in the sexual organs, are coincidences or accidents only.

553. *B. The morbid condition more immediately occasioning the malady* seems to consist of increased nervous susceptibility and greatly impaired power, frequently associated with deficiency of blood. The balance of the circulation is also often disturbed, and irregular determinations of it take place, especially to the brain, and to the uterus. Whilst the circulation is more active in one quarter, it is deficient in others, and the functions of the brain are thus directly or sympathetically disordered. — After impregnation, the organic nervous influence of the uterus and ovaria is more or less developed and exalted, and the excitement of these organs often extends to, or reacts upon, the cerebro-spinal nervous system, and its manifestations, exciting and disordering it and its functions. After delivery, the susceptibility of the brain, and of the nervous system generally, is increased, and the disposition of these to be sympathetically affected by the states of the mammæ, uterus, and ovaria proportionately augmented, — the susceptibility being great in proportion to the shock which the system has sustained from the parturient process, and to the loss of blood and exhaustion. The occurrence of the disease during lactation is to be imputed chiefly to exhaustion, debility, and vascular inanition; and its appearance after weaning, to a disturbance of the balance of the circulation,— a greater determination of blood taking place to the brain than to other parts, upon the cessation of the secretion of milk, as well as upon the premature cessation of the lochia.

554. vi. TREATMENT. — *A.* Insanity occurring *during pregnancy* is generally either partial, or of short duration when it assumes a maniacal form. In either case, the treatment should chiefly depend upon the state of the vascular system as to fulness, action, and tone. When the circulation is deficient in none of these conditions, and particularly when plethora exists, a small bloodletting will then be useful; but in doubtful, or other circumstances, cold applied to the head, warm and stimulating pediluvia, refrigerants, and refrigerating diaphoretics, cooling aperients, and antispasmodics, conjoined with narcotics, as hereafter prescribed, must constitute our principal means of cure; aided, however, by judicious moral management, and by appropriate diet and regimen.

555. *B. Insanity occurring soon after parturition* requires the utmost discrimination in ascertaining—1st, the presence of the disease in its pure or unmixed character; — 2dly, those mixed states which partake either of the character of phrenitis, or of that of low nervous fever: and the greatest care in the selection of remedial agents. In this disease it is always most important to consider the state of the vascular system, in connection with nervous excitement; and to inquire as to the dependence of whatever degree of vascular action that may be present upon the condition of the nervous system, and upon the mental disorder and muscular efforts. In all cases, moreover, it should never be overlooked, that the frame has received a shock, during the parturient process, — that the nervous system has endured great excitement and suffering, — and that the vascular sys-

tem has sustained a loss sufficient in many cases seriously to disturb the healthy relation subsisting between the state of the vessels and their contents, and to disorder the balance of the circulation in different parts of the body. These considerations will generally guide the practitioner in the treatment of the more difficult, doubtful, or mixed cases: the more simple and pure instances of the disease will present neither difficulty nor doubt.

556. *a. Bloodletting*, in any mode, is most injurious in puerperal mania and melancholia, and in such cases as are attended by fever; or, where the symptoms approach those of delirium tremens. Indeed, puerperal insanity occurring in the lower classes of society, not infrequently, is very closely allied to that disorder, owing to the circumstances already noticed (§ 546. 551.). In those cases which assume the form of *nervous fever*, vascular depletion is also pernicious. Where, however, the malady approaches, in some of its features, a *phrenitic form*, — when the head is hot, the face flushed, the pulse hard or strong, and the secretions suppressed, the propriety of bloodletting might seem to be obvious; yet, even in these cases, the practice, although cautiously resorted to, might be injurious, or fail of proving beneficial. Those symptoms are sometimes fallacious; for they are occasionally produced by the violence of the nervous and mental excitement, or of the physical exertion, relatively to the power of the system, and are of short duration, — dangerous exhaustion soon supervening. In such instances, even a small bloodletting would only hasten and increase the consequent depression. In cases, which commence with headach, fever, flushing of the face and eyes, diminished secretion and excretion, and occasionally preceded by chills or rigors, and in which the mental disorder is clearly consequent upon the inflammatory and febrile symptoms, a recourse to bloodletting, and to other antiphlogistic means, is obviously requisite, for the disease is more or less inflammatory, or consists of a state of active congestion, approaching inflammation. Yet, even in these cases, the practitioner will be guided, in some measure, by the rapidity with which the mental disorder followed the physical disturbance, by the previous condition as well as the existing circumstances of the patient, by the evacuations attending and consequent upon parturition, and by the several phenomena characterising the case. Whenever the mental affection follows quickly upon the cerebral and constitutional symptoms, vascular depletions of any kind are seldom of service, unless very prudently prescribed.

557. When there are much heat of the scalp, flushing of the face, beating of the carotid arteries, and no indication of urgent debility or exhaustion, the previous condition and evacuations of the patient furnishing no sufficient reason for the existence of these states, then may leeches be applied behind the ears or around the occiput, and cold to the head, with great advantage. Whilst ice, cold lotions, &c. are placed around the shaved head, the feet and legs should be frequently bathed in warm water, to which mustard, or scraped horse-radish, has been added. In the majority of cases, where inflammation is dreaded after delivery, there is only active determination of blood to the head, the circulation in the extremities and in other parts being impaired; and in these the continued application of cold to the head, and the frequent or persevering use of derivatives to remote parts, or to such as experience an insufficient supply of blood, will generally remove the disorder. The application of blisters to the nape of the neck has been advised by many, but they are seldom of much service in the maniacal states of disorder. In the melancholic form, or when there is a tendency to stupor, rather than to high excitement, blisters on the nape, or behind the ears, are generally of use.

558. *b.* In a great proportion of cases of puerperal insanity, fæcal accumulations have formed in the alimentary canal, and morbid secretions have collected in the gall-bladder, hepatic ducts, in the cæcum, and in the cells of the colon. The existence of these collections is indicated by a loaded, foul, or furred tongue, by a fœtid breath, by a lurid or discoloured state of the skin and of the complexion, by more or less fulness in the regions of the cæcum and sigmoid flexure, and by dark and offensive evacuations. The propriety of *purgatives* in all such cases, and of *emetics* in many of them, is undoubted. The latter, however, should not be used when debility or exhaustion is extreme, — when the face is pale, the skin cold, and the pulse very quick and weak. Ipecacuanha is the best emetic in ordinary circumstances; but when vital depression is considerable, any of the warmer emetics prescribed in the *Appendix* (F. 402, 403.) may be used. After its operation, calomel may be given with camphor and some cathartic extract, and a few hours subsequently a draught, with rhubarb and magnesia, or any other purgative, may be taken. The full operation of these upon the bowels should be secured either by their repetition, or by the administration of enemata, and especially of those containing castor oil and spirits of turpentine. In most cases, the stomachic aperient, consisting chiefly of the compound infusions of gentian and senna (F. 266.), or the compound aloetic pill or decoction, will be the most appropriate medicines.

559. *c.* Having evacuated morbid secretions and fæcal collections, it is next requisite to support the constitutional powers and allay nervous excitement by *antispasmodics* or *diffusive stimulants*, conjoined with *narcotics* or *sedatives*. Where debility, exhaustion, or vascular inanition, is urgent, it will generally be necessary either to combine restoratives or stimulants with alvine evacuants, where the latter are requisite, or to give the former in the intervals between their exhibition. — *Narcotics* are more beneficial in puerperal, than in any other form of insanity, particularly when conjoined with camphor, ammonia, or aromatics. Since 1815, I have usually prescribed five grains of the extract of *hyoscyamus* with an equal quantity of *camphor*, in the morning and afternoon, and double this quantity of each at bed-time. Where there are much heat of the head, flushing of the face, and thirst, these symptoms should be removed by cold applications, purgatives, refrigerants, and external derivatives, before camphor or ammonia is exhibited; but notwithstanding their presence, in a moderate degree, the camphor and hyoscyamus may be exhibited, provided that these means are persisted in, and the enemata already advised are occasionally administered. In still more urgent cases, the camphor may be given

more frequently, conjoined either with hyoscyamus or with *opium* or *morphia*, — a larger dose being given shortly before bed-time. I have rarely found the following draught to fail in giving repose, and in contributing to the clearing up of the mind subsequently, when prescribed after the requisite alvine evacuations, and when the head is kept cool, and the lower extremities warm: the enema has also proved very generally of service.

No. 277. ℞ Morphiæ Acetatis gr. ⅓; Liquoris Ammoniæ Acetatis ʒ jss.; Mist. Camphoræ ℥ j.; Acidi Acetici ♏ vj.; Spiritûs Lavand. Comp., Spir. Myristicæ, Spir. Rosmarini, āā ʒ ss.; Syrupi Papaveris ʒ j. M. Fiat Haustus, horâ somni sumendus.

No. 278. ℞ Camphoræ rasæ gr. x.; Assafœtidæ ʒ ss—ʒ j.: Extr. Rutæ ʒ ss.; tere cum Olei Terebinthinæ ℥ j.; Olei Ricini ℥ j. (vel Olei Olivæ ℥ iij.); Decocti Avenæ ℥ x. ad ℥ xiv.; Syrupi Papaveris ʒ ij. ad ℥ ss. Fiat Enema, pro re natâ injiciendum.

560. *d.* It is important *to administer due support to the system during the treatment of the disease*, more especially when there is neither a febrile state of the pulse, nor heat of the head or surface; and this support, whether *medicinal* or *dietetical*, should have due reference to the previous modes of living and habits of the patient. When puerperal insanity becomes chronic, or when it appears in the course of suckling, and particularly when there is a total absence of inflammatory or febrile symptoms, *tonics* — especially the infusion or decoction of *cinchona*, or any of the *bitter infusions*— may then be given with *ammonia* and *aromatics*; the secretions and excretions being promoted by the usual means; change of air and of scene, and appropriate moral treatment, being brought in aid of the physical remedies. When the patient has been addicted to the use of intoxicating liquors, and especially if the disease assume a form approaching to delirium tremens, then *opium* with *camphor* or with *ammonia* should be freely administered. *Brandy* or *wine* may be given in arrow-root; or even *warm, spiced,* or *mulled, wine,* or *ale*, may be occasionally allowed.

561. *e.* The *diet* requires much attention. Drs. Prichard and Gooch remark that patients incur some risk of being starved in this disease, through the mistaken notions of their attendants, who are apt to consider the excitement of the malady a reason for withholding food; when this very state, owing to the exhaustion often produced by it, renders due support especially necessary. Farinaceous fluids of a nutritive quality, as rice, arrow-root, sago, &c., should be given at short intervals, when febrile symptoms preclude the use of animal food. Warm milk, or broth, may also be allowed, but should be taken in small quantity at one time. In protracted cases, solid meat, malt liquor, wine and water, bottled porter, or the bitter ale usually sent to India, will often be of service. Patients who have been accustomed to live fully, and to the use of stimulating liquors, must be allowed such food and beverages as their physical symptoms will permit, without reference to the state of the mental disorder. When suckling is concerned in producing, heightening, or perpetuating the mental affection, by draining an already weakened constitution, a nurse must be procured, and a nutritious and tonic diet and regimen prescribed, with change of air, and the use of chalybeate waters.

562. *C.* When *insanity appears during suckling*, the treatment is nearly the same as that just described. A nutritious and cordial *diet* should be immediately allowed; and meat taken daily, with about four ounces of wine. Purging in such cases is injurious, but the bowels should be kept in a regular state by the compound decoction of aloes, or by the infusions of gentian and senna. If the mental disease occur after sudden weaning, and particularly if it assume a maniacal form, and if there be any reason to infer that an inflammatory affection of the brain has supervened upon the sudden suppression of the milk — if the symptoms already mentioned, as indicating this state, appear, then appropriate means should be prescribed; but this is not to be determined, nor is the treatment to be regulated, by the disorder of the mind, but by the bodily symptoms.

563. When the *milk* becomes scanty, or ceases to be secreted, and the mental disorder seems to be aggravated by this circumstance, or has supervened upon it, the secretion should be encouraged by keeping the child to the breast.—If the *lochia* disappear prematurely, means should be taken to procure its return. For this purpose, the warm bath, the semicupium, or the hip bath, may be used; and, if these fail, leeches may be applied on the insides of the thighs, near to the groins, and the hip bath be subsequently employed. Warm fomentations may also be applied to the pudenda, or over the pubes. At the same time, cold applications around the shaved scalp ought to be assiduously employed.

564. The *constant attendants* on the patient should control her mildly but effectually, not irritate her, but protect her from self-injury. Servants or monthly nurses can seldom do this; they ought, therefore, to be removed, and a nurse accustomed to the care of deranged females placed in their stead. The patient should never be left alone; and every thing with which self-injury can be effected should be carefully removed. The windows ought also to be secured. The husband or near relations ought never to be left alone with the patient, but should be excluded until the state of the disorder permits their admission. It is generally necessary to remove all persons who are sources of excitement of any kind. Seclusion in some mode or other — partial or complete — is generally necessary, — at least, for some time. There is often, however, great difficulty in carrying this into effect, in such a way as will tend to the comfort and speedy recovery of the patient. Removal to an asylum is not so frequently requisite for the mental disorders of puerperal patients, as for insanity occurring in other circumstances. It is principally required in the more obstinate and prolonged cases; and after other measures of partial or complete seclusion have been tried. Dr. Gooch remarks, that, where seclusion has been adopted, there may come a time, at which some interruption to this solitary life may be advisable. When the disease has lasted long, when the patient expresses a strong wish to see some near friend, when she entertains illusions which the sight of some one may efface, the admission of such person should be tried. It is well observed by Dr. Haslam (*Moral Management of the Insane*, p. 14.), that confinement is too indiscriminately recommended and persisted in. An intercourse with the world has dispelled, in many instances, those hallucinations, which a protracted seclusion, in all pro-

bability, would have added to and confirmed. In its passive state, insanity has been often known to wear off, by permitting the patient to enjoy her liberty, and to return to her usual occupations and habits. There is obviously a period of the malady approaching convalescence, in which the bodily disease is loosening its hold over the mental faculties, and in which the latter are capable of being drawn out of the former by judicious appeals to the mind, and by a salutary moral management.

XI. SUICIDAL INSANITY. SYN. — SUICIDE — SELF-HOMICIDE; *Suicidium, Autochiria; Melancholia Suicidium; Selbstmord*, Germ.; *Le Suicide*, Fr.; *Suicidio, Suicida*, Ital.

565. Under *suicidal insanity I proceed to consider self-destruction or self-homicide, whether it be seriously entertained, or attempted, or perpetrated.*

566. The religion, the laws, and the manners of a people contribute in a remarkable degree to the opinions entertained respecting suicide, and to the frequency of it among them. Of the influence of the laws on self-destruction, sufficient proofs have been furnished in recent times; and the restraints formerly imposed by them, upon minds insufficiently influenced by rational views of religion, being now in a great measure removed, this crime has become much more common, and has assumed an importance equally great, in a moral and social, as in a strictly medical, point of view.

567. The *Ancients*, in general, condemned suicide, unless on occasions calculated to benefit the common weal. Several stoical writers, however, attempted to justify it by reasoning and by their examples, whilst the opinions of others respecting it were either contradictory or insufficiently expressed. *Legislation* regarding it was formerly, and still remains, very different in different countries; it being in some places allowed by the laws, in others tolerated only in certain circumstances, and in some condemned as a crime. The *Christian religion*, of whatever sect, and the doctrines of the Koran, regard it amongst the greatest of sins; whilst it is permitted, or even encouraged, by numerous pagan rites. At the present day, the *opinion* *, by no means generally received, although very commonly acted upon in this country, that suicide is always an insane act, leaves every member of the community at liberty, without any degrading penalty attached to the act, to dispose of his own life as he pleases, without reference to the claims of those depending upon him, or of society in general. The knowledge that no indignity will result to his body, and no discredit to his memory, thus becomes an incentive to self-destruction; and, even when it is not an incentive, it cannot, at least, impose any restraint upon an impulse to commit this act, when a weak-minded person is subjected to chagrin, passion, and misery.

568. That suicide is frequently, or even generally, caused by some one or other of the numerous forms of insanity, may be admitted; but that it is thus occasioned in all cases, is not so manifest. It may be said, that it is an act of moral insanity; and, as far as immorality and passion may be viewed as temporary insanity, so far may it be considered as such. But that it alone constitutes insanity, or that, in a considerable proportion of the cases of it, — especially those wherein mental sanity has been disputed, — the mind is disordered even to the extent contended for, in respect to the forms of moral and partial insanity described above, is not so evident. That the mind is impaired, and the judgment so far weakened, as to be swayed by morbid feelings and impulses, or to be unable to withstand the suggestions of passion and chagrin, may be allowed; and, as far as a weakness of mind, permitting the impulsions of passion their full career, may be considered as insanity, so far may suicide be viewed in this light. We observe the mind of the petted and spoilt child to have the weakness and susceptibility natural to the early stages of its developement increased by the indulgence, and remark the effects produced upon it, when a desired object is withheld. In like manner, the adult mind, unexercised and imperfectly strengthened by opposition and disappointments, and pampered by enjoyment and success, experiences a sudden revulsion upon unexpected reverses or indignities, is thereby irritated as well as depressed, and accuses itself or Providence, — the impulses excited by these feelings being sometimes carried into effect before the sober dictates of reason can withstand them; or these impulses more or less quickly overthrow the efforts which reason may make. In most cases, these efforts are too feeble to counteract the impulses arising out of outraged feelings, or to subdue the sufferings of wounded self love, or the stings of injured honour. The mind, already weakened by indulgence, is the easier overwhelmed by these emotions, the more intensely feels the shock, more quickly sinks before it, and is the less capable of making an effort to recover itself, the less it is swayed by the dictates of religion and principle, and the less it is deterred by fears of any indignity, or of the reprobation of opinion. All these sentiments come in aid of the mind in adversity, or during contrarieties, when duly regulated, although weakened, and conduce to a healthy moral reaction; but they can have no influence where they have never been habitually entertained.

569. i. OCCASIONS OF SUICIDE. — *A. The exciting causes, or the circumstances determining self-destruction*, are very diversified. Whatever may be the motives or incentives to this act, they promise to the imagination something preferable to life, or a lesser evil than existence. — 1st. Suicide may be committed in circumstances, or with motives, calculated to excite admiration, or, at least, to preclude the imputation of blame; but such occasions are rare; and although not infrequently recorded in ancient history, they rarely or never occur in modern times, or in the present state of society. — 2dly. Suicide is often caused, in some countries, by religious rites or institutions, by received notions respecting injured honour, and by hopes of thereby passing into a happier state of existence. — 3dly. It is very frequently occasioned, in barbarous communities, by a species of nostalgia, by forcible removal from home, or by slavery, and by ill-usage, in connection with a belief of thereby returning to former abodes in another state of existence. — 4thly. It occurs very frequently during delirium and mania, — in consequence generally of some illusion, false percep-

---

* In respect of suicide, opinion is as strong as a legislative enactment, inasmuch as it determines the coroner's jury as to their verdict, — this act being always found by them as that of insanity.

tion, or error of judgment. — 5thly. During melancholia, it is very commonly attempted; and the idea of committing it is generally entertained long before it is perpetrated. — 6thly. It is sometimes also attempted in almost all the other forms of partial insanity, and particularly those attended by depression and anxiety respecting a state of future existence, or by unsettled views of religion. — 7thly. Suicide often is suggested by the emotions consequent upon reverses, wounded self-love, chagrin, and contrarieties of all kinds; and by the violence or intensity of passion and anger: the enraged feelings, being incapable or unable to exhaust themselves upon the object which excited them, recoil upon themselves, and often thus originate a suicidal impulse, which is not always successfully resisted. — 8thly. A suicidal suggestion may arise from various circumstances of a negative or passive kind, — from satiety, from ennui, from the want of excitement, from the excess of gratification, and the exhaustion of all its sources, &c. In such circumstances, the idea may long be entertained, and, ultimately, either carried into effect, or laid aside, from a change in the mental or physical state of the individual. — 9thly. It may proceed from a mental infection or sympathy, — from the details, contained in the public caterers to the gratification of the more debased of our moral sentiments, of various modes or instances of self-destruction, — and from a desire, during states of chagrin or disappointment, of obtaining notoriety by the manner of carrying it into effect. — 10thly. It is often committed in order to avoid public exposure and ignominy, or punishment of a severe or lasting kind. — 11thly. It is more rarely had recourse to, in order to escape from violent pain, or the various miseries attending want and destitution, and from feelings of despair. — 12thly. From remorse or self-reproach. — 13thly. From a morbid or insane impulse, without any other obvious mental disorder. — 14thly. From a species of fascination, — as when looking down from great heights. — 15thly. By weak minds in a state of irritation and chagrin, in order to injure the feelings, to occasion regrets, and thereby to revenge slights or contrarieties on those who caused them. — 16thly. Suicide may be mutual and reciprocal, caused by the same feelings, and by the same or different means. — 17thly. It may follow murder. — 18thly. It may be simulated. — Certain of these require further remark.

570. *a.* The instances of self-destruction or of self-devotion caused by patriotism, or by a wish to benefit the community, or to escape dishonour, have been generally viewed as precluding blame, and as hardly deserving to be ranked as suicidal. The cases of CODRUS, of DECIUS MUS, of CURTIUS, of OTHO, of the citizens of Calais and of Rouen, may be referred to as being of this kind. ZENO and his followers inculcated, that a wise man should be ever ready to die for his country or his friends: and the Stoics in general taught, that suicide was preferable, not only to dishonour of any kind, but even to the enduring of severe pain, or lingering disease. Amongst the Greeks and Romans, self-destruction was preferred by many to subjection to a victor, or to a state of slavery. ISOCRATES, DEMOSTHENES, BRUTUS, and CATO terminated their own lives rather than fall into the hands of conquerors.

571. THEOXENA and the virgins of Macedon committed suicide to escape dishonour; and numerous instances of a similar kind have occurred in ancient and modern times. LUCRETIA would not survive the dishonour she could not prevent. LYCURGUS and CHARONDAS sacrificed their lives in order to maintain the inviolability of their own laws and institutions. Most of the above instances of suicide may be viewed as precluding blame, and some of them may claim our admiration. But other instances, committed on less laudable occasions, have been considered as excusable by MONTAIGNE, Dr. DONNE, ROUSSEAU, HUME, and others. When JOSEPHUS, who commanded the Jewish army, wished to surrender to VESPASIAN, from a conviction of the hopelessness of resistance, his soldiers insisted upon their having recourse to suicide rather than to yield to a conqueror. But he resisted their importunities, and concluded his arguments by observing that "self-murder is a crime most remote from the nature of all animals, and an instance of impiety against GOD our Creator."

572. *b.* The victims of religious rites, as in India, and in the Canaries in former ages — of national customs and manners, as in the isle of Ceos, Japan, &c. — and of ignorance — and of those persuasions which constitute a part of religious belief, also, — are not be viewed as instances of suicidal insanity, but as proofs of the influence of high moral and religious considerations and expectations, of the tyranny of custom, and of false notions of honour; and they result legitimately from the training or education of the mind from an early period of its developement. They are altogether different from the suicides which were so frequent during the decline of Roman greatness, and which proceeded chiefly from vice and licentiousness, or rather from the sentiments and impulses which are generated from these sources — sources so productive of suicide in some countries at the present time.

573. *c.* Suicide in states of *mania*, or of *delirium*, occur either from some involuntary or blind impulse, or from some delusion, hallucination, or false perception, — as when a person, in either of these states, throws up the window of his room, and walks out of it, in the persuasion of his going out at the door. Maniacs also attempt to destroy themselves at the commencement of the malady, under the influence of the moral despair which caused it; and others commit the act from the distress caused by a knowledge that the disease is approaching or is returning. A patient for whom I was consulted during an attack of mania, from which he recovered, experienced, after a time, similar symptoms to those which ushered in the former attack. His friends were directed to take the necessary precautions regarding him; but these he eluded, and committed suicide. This act is occasionally also attempted during convalescence from mania, in consequence of reflecting upon the excesses committed during the attack. It may even be accidental, owing to attempts at escaping from restraint or seclusion.

574. *d.* In *melancholia* and *monomania*, suicide is occasioned by illusions, or by the violence or intensity of some passion or sentiment, or by a sudden impulse which reason is incapable of restraining, or which induces the act before reason can be exerted, as more fully explained above

(§ 91, 92.). In some cases, the morbid impulse is partially or fully carried into effect; and either in consequence of the nature of the means of self-destruction employed, or of reason having at last come to the rescue, attempts are made by the individual himself to counteract them; these attempts either succeeding or not according to circumstances. The suicidal impulse is occasionally developed in an early stage of congestion of, or of inflammatory determination of blood to, the brain; and either previously to, or contemporaneously with, such impulse, insane delusions or acts may be manifested. If, in such cases, the means of destruction shall have the effect of removing the morbid physical condition before extinguishing life, the patient will make efforts at self-preservation. This is not infrequently the case, when suicide is attempted by dividing the vessels in the neck. When self-murder is resorted to, during melancholia, from a fear of becoming insane, and with the feeling that it is the patient's fate or destiny to commit it, the conviction is sooner or later completely verified. Indeed, when it is contemplated or attempted in any form of partial insanity, the intention is generally persevered in, although it may be variously concealed, until it is accomplished in one way or another.

575. In melancholia and other states of partial insanity, or even previously to any symptom of insanity being sufficiently prominent to attract notice, or in consequence of some mental shock or perturbation, the patient may conceive that an internal voice calls upon him to commit suicide, and may act in conformity with it; or he may entertain the idea long afterwards, either without being able to divest his mind of it, or resisting the impulse to perpetrate it with the greatest difficulty, and with the utmost exercise of his reason. A lady consulted me on account of headach, during which she could not look upon a knife without experiencing a strong desire to use it against her own life; but her reason had always resisted the impulse, which disappeared after treatment. In such cases, if medical and moral means be not appropriately employed, and often notwithstanding the aid of both, the morbid impulse is ultimately carried into effect. Amongst persons who have been but little accustomed to self-control, or to listen to the dictates of moral and religious principles, such impulses are often soon acted upon. M. Esquirol furnishes several instances. A monomaniac, he states, heard a voice within him say, "Kill thyself, kill thyself!" and he immediately obeyed the injunction. This writer remarks, that he has never known an instance of suicide from an irresistible impulse, without some secret grievance, real or imaginary, serving as motives to the suicidal propensity. There are few states of *partial insanity*, that may not be attended, or followed, by this propensity. Of the delusions which characterise melancholia, there are none more productive of self-destruction, as Dr. Darwin has remarked, than the fear of future damnation, and of present poverty.

576. *e.* Suicide may be committed under the influence of *passion*, of *violent anger*, or of *self-accusation or remorse*. When intensely excited by anger, the mind, for the time, is in a state truly maniacal; and acts of violence to others, or to the person himself, may be committed in the height of the paroxysm, according to the nature of the circumstance or occurrence causing the excitement. Suicide from this cause is most likely to be the fate of those, who have not been sufficiently taught to curb their feelings, and who have been improperly indulged in early life — as Childe Harold describes himself, —

> "My brain became,
> In its own eddy boiling, and o'erwrought,
> A whirling gulf of phantasy and flame:
> And thus untaught in youth my heart to tame,
> My springs of life were poisoned."

Remorse and self-reproach frequently lead to self-destruction, as the only mode of escaping from the enduring agonies they occasion. The passions which "madden to crime" are often followed by the most anguishing feelings of self-accusation, which not infrequently arm the hand of the sufferer against his own existence. Shakspeare has powerfully and naturally illustrated this state of mind in his delineation of the character of Othello. The victim of remorse is often haunted by dreams, from which he awakens in a state of frenzy, or of delirium, in which attempts at suicide are sometimes fully carried into effect; and in his waking hours his mind is haunted by recollections which become his domestic Furies, and lash him on to madness. "Sua quemque fraus," says Cicero, "et suus terror maxime vexat; suum quemque scelus agitat, amentiâque afficit; suæ malæ cogitationes conscientiæque animi terrent. Hæ sunt impiis assiduæ domesticæque Furiæ." But, whilst remorse thus leads to suicide, by at first more or less obviously disordering the mind, this act as frequently is the proximate result of the moral sentiment; the attempt, or the commission of it, being preceded by no other morbid manifestation of mind than the moral torture proceeding from the consciousness of having committed a crime, great either in itself or in relation to the various circumstances connected with it.

577. *f. Reverses, mortified pride,* impatience under misfortune, and *disappointments*, are frequent causes of suicide, especially in commercial countries, and under free governments, where there is a constant straining, amongst the more educated classes, after wealth, honour, and other direct or indirect means of power. Many of the ancient as well as modern instances of self-murder are to be attributed as much to the effects of reverses and mortified pride upon the mind, as to the higher motives to which this act has been referred. The suicides of Brutus, Antony and Cleopatra, and of Petronius and Sardanapalus, may be viewed in this light. Instances of self-destruction from mortified pride, consequent upon the failure of attempts at becoming conspicuous at public meetings, in the senate, or at the bar, or even upon the boards of a theatre, are not rare in modern times. The passion for notoriety too frequently entertained by silly or weak persons, when suddenly or rudely humbled, is often followed by a state of extreme mental collapse or depression, which sometimes terminates itself in suicide. The shock produced by the failure of long or warmly cherished hopes, of whatever kind, either suddenly overwhelms all efforts of reason and judgment, — the suggestions and impulses of passion and feeling being followed without control, — and thus induces at once a state of moral insanity as harbingers of the

suicidal act, or more slowly and surely developes some one or other of the forms of mental disease above described. In either case, the entertaining of the idea of self-destruction is an indication of insanity, inasmuch as it is connected with, or dependent upon, an overthrow of reason and judgment in the one, and a manifest disorder of mind in the other. But, in many instances, the act is perpetrated after the first shock of a reverse or disappointment has subsided — after reason has resumed her sway, and has been more or less exerted in calmly combating the feelings and suggestions, which such reverse may have called into activity. In these cases, the suicidal act is the result of a weighing of the present and consequent misery — of the wretchedness attending upon existing and prospective emotions, against the contingencies following the commission of this crime; and whatever of insanity may be present, consists only of the excessive emotions which reverses occasion, relatively to the strength of moral and religious principles by which they are, or should be, controlled. Hence it follows, that a number of suicides are committed after disappointments, losses, &c., in a state of mind not absolutely amounting to insanity — during an impatience under misforture, unrestrained by these principles, owing either to their weakness or absence. Various kinds and grades of disappointment or misfortune will lead to the commission of this crime, according to the susceptibility of the mind, the early education, the previous trials and tutoring of the understanding, the preceding career of success or amount of distinction, and various accessory circumstances connected with existing states of society and manners. The most common, however, are losses of fortune or of reputation, losses from gambling or from transactions of this description, moral and worldly humiliations, disappointed affection, and the losses of friends, — several of these being combined in their operations upon the mind.

578. *g.* One cause of suicide, of no infrequent occurrence in the present state of society, has been insufficiently considered by medical as well as psychological writers: this is, the *satiety* and *ennui* consequent upon excessive sensual gratifications, felt by minds imperfectly, or viciously educated, and unaccustomed to those pains, privations, and contrarieties of life, that impart happiness to the enjoyments by which they generally are sooner or later followed. Continued and excessive gratifications destroy the susceptibility and excitability of the nervous system, and exhaust its manifestations. The languor consequent upon enjoyment is not allowed to subside, or to be succeeded by renewed vigour, before the indulgence is repeated; and as languor and exhaustion increase with the repetition of the gratification which occasioned them, so the desire of escaping from these unpleasant sensations becomes also increased, and the want of varied and augmented excitement is experienced. Thus gratification begets desire, and desire calls for gratification, until all its sources are exhausted, all its varieties and grades are enjoyed; and the sated mind, no longer finding objects capable of exciting it, or of enabling it to emerge from the languor or depression consequent upon inordinate enjoyment, and deriving pleasure no more from the numerous sources which afford it to better regulated minds, feels most bitterly that "all is vanity and vexation of spirit." In the career of gratification, moral and religious principles are gradually at first departed from, and ultimately altogether despised; and once the mind is no longer able to receive enjoyment from the usual means, and has exhausted all the sources of it, within its reach, it has also approached the lowest grade of moral degradation, which either takes refuge in suicide, or is ready to have recourse to it, in moments of deep depression, or on occasions of severe contrariety or disappointment. The restraining influences of principle, and of regard to reputation, have ceased to influence the conduct; and, as soon as the continued and varied indulgence has exhausted vital and mental power, and dried up every spring of enjoyment, circumstances which depress, or vex the mind, will often give occasion to suicide, or suggest it; or the mind, no longer being capable of gratification, entertains at first the idea of suicide, and ultimately has recourse to it, in order to escape from the misery of the extreme languor which it is incapable of dissipating.—Whilst most of the causes of suicide, and especially those already noticed, are of an *active* kind, this may be viewed as altogether *passive*. Whilst the *former* act by violently exciting and disturbing the mind, the *latter* results from a defect of such excitements as will rouse it, and afford those gratifications, without which it either cannot exist, or prefers not to exist at all.

579. It has been said, that a Society for the mutual Encouragement of Suicide exists in Paris, the members of which undertake to terminate their own existences when life becomes insupportable; and the circumstance is almost verified by the character of the prevailing literature, and of the drama, in that capital. Numerous are the instances, not only throughout France, but also in this country, of persons who, having run an unbroken and rapid career of sensual gratification, and either exhausted its sources or their own means of enjoyment, have therefore put a period to their existence without any further reason, and without any previous proofs of their insanity beyond the inordinate indulgence of their desires and passions, and the predominant sway these had obtained over all their sentiments and actions.

580. *h.* Closely allied to the preceding is the occurrence of a *morbid* or *irresistible impulse to commit suicide*, without obvious mental disorder, or any moral cause sufficient to account for the act. Suicides of this kind occur most frequently in persons belonging to families hereditarily prone to insanity or suicide; and hence, in some instances, may be viewed as the first manifestation of the mental disorder. But they likewise are committed by persons who are not thus predisposed, and under circumstances which require a brief examination. — 1st. From a species of *mental sympathy or infection*, caused by perusing the details of cases of suicide furnished so circumstantially, and injuriously as respects the minds of the community, by the weekly and daily press. Instances are often occurring, of not one only, but of several suicides being committed during the first few days following the publication of some notorious case of self-murder — notorious as respects either the rank of the individual, or the mode of perpetrating it, or other circumstances connected with it. Such instances have been long remarked, and are of

increasing frequency owing to the existing state of society, of which some notice has already been taken (§ 272. 320.), and to which a brief reference will hereafter be made.—2dly. Suicide is, in rare instances, perpetrated from a species of *fascination*. The very knowledge of having in hand the means, or by a single step the power, of self-destruction, may give occasion to the impulse of committing it, which may even be instantly carried into effect by the weak, susceptible, or the morbidly disposed mind. I have had, on several occasions, to prescribe for highly nervous persons — those labouring under a morbid sensibility of the nervous system, and anxious susceptible states of the moral feelings — who could not handle a razor or sharp knife without being distressed by the desire or the idea of attempting suicide. Such persons, also, are unable to look down from great eminences, or over a precipice, without experiencing a desire of throwing themselves headlong. Byron has noticed this feeling, and ascribed it to

> “ The lurking bias, be it truth or error,
> To the *unknown;* a secret prepossession,
> To plunge with all our fears — but where? you know not,
> And that 's the reason why you do — or do not.

The bias to the unknown, here noticed by the poet, has little or no influence in originating this singular feeling, which is sometimes experienced by persons, both physically and morally sane, as well as by the weak in mind and body. This desire or impulse to precipitate one's self, when looking downwards from a very high precipice, obviously arises from no process of reasoning. Probably the suggestion of contrast may be concerned in producing it; and something may be owing to the unusual impression made upon the mind through the sense of sight — to the nature of the sensation itself. That this sensation is even pleasurable, — that it is attended by a sort of fascination,— is admitted by those who have experienced it; and, with many persons, the desire is so strong as to require the active exertion of reason to overcome it. That it causes a physical as well as a moral effect, — that it affects the circulation in, as well as the manifestations of, the brain,— is shown by the vertigo which accompanies it, and which often occurs without the desire of self-precipitation or destruction. Indeed, I doubt much, whether or not the feeling produced in the mind by this impression on the sense of sight is *primarily* attended by such a desire. It would seem, that the sensation is pleasurable, and that it excites a desire to throw one's self headlong in the gratification of it. But reason immediately dictates, that this act would be attended by self-destruction; and from this the sane mind recoils with a shudder — recoils from the consequences of enjoying the feeling which the nature of the sensation had thus suggested. This subject, although noticed by Falret, Andral, and others, has not been hitherto investigated with reference to suicide. But it is not improbable, that persons who have entertained the idea of self-murder, and yet have not been able to summon resolution to commit it, knowing the influence of the sensation of looking down from a precipice upon the mind, have had recourse to it, in order to aid their weak resolves. Others, probably, in states of high susceptibility and extreme weakness of the nervous power, have followed the impulse or fascination thus produced, before reason had time, or recovered power, to counteract it.

581. *i.* Suicide may, under certain circumstances, become almost *epidemic*. Indeed, an epidemic prevalence of the act has been noticed, without any other causes, besides those just stated, to account for it. Sydenham has mentioned such an occurrence, and others have taken place in more recent times. During the atrocities of the French revolution, — atrocities the most humiliating in the history of the human mind, — the “ damned spot” in the annals of France, which neither her science can obliterate, nor her military glory can conceal, — suicides were most prevalent, owing to a variety of causes, and often to a combination of circumstances and feelings, — the loss of honour, fortune, and friends; the impulses of passions, and of remorse, despair, &c. The frequency of suicide at certain periods, and in particular places, is caused chiefly by political changes and by commercial crises, affecting the position of numerous individuals in society, mortifying their pride, and changing their prospects. Something, also, may be imputed, on certain occasions, to *mental sympathy* or *imitation*, and somewhat even to a passion for *notoriety;* but impatience under misfortunes and disappointments is the most common cause. M. Andral states, as proving the influence of imitation in causing suicide, that one of the inmates of the “ *Invalids*” was found hanged in a particular corridor. Two days afterwards, a second was found in the same place; then a third, and even a fourth. This corridor was shut; after which no more hanged themselves. He further remarks, that, not long ago, it was the fashion for people to throw themselves from the top of the column in the Place Vendôme. This was, however, only a fashionable mode of committing an act which is always common in Paris, and which was not the more frequent because this mode was preferred to the other means more usually adopted. It has often been noticed, in most civilised as well as uncivilised countries, and particularly in communities closely associated by feelings and interests, as in regiments, &c., that a single instance of self-murder is soon followed by many.

582. *k.* Self-murder has been often perpetrated in order to *escape exposure* and *punishment* consequent upon detected crimes. Indeed, this is one of the most common moral causes of suicide in this and other civilised countries, and instances of it are of daily occurrence. Many of the actors, and prime movers, in the unprecedented atrocities of the French revolution, committed or attempted suicide, when they came in their turn to experience a direful retribution. Criminals of all grades, from the petty depredator to the state delinquent, have sought refuge in self-murder, from the accusations of conscience, the shame of exposure, and the extreme wretchedness attending conviction and the last penalties of the laws. — Detection of, as well as remorse caused by, *conjugal infidelity*, has been followed by suicide. In the one case, this act is resorted to in order to avoid the exposure and shame consequent upon detection, although remorse influences the mind in part to form the resolution; in the other, self-reproach is often the sole cause.

583. The desire of escaping from *moral* or *physical pain*, or from *anticipated* or *impending want*, is not infrequently productive of self-de-

struction. Under this head may be comprised *seduction*, and *despair*, however produced. How numerous are instances of suicide caused by the despair consequent upon seduction, the desertion of the seducer, and all the contingent miseries, heightened by the fears and anticipations of the seduced, by the desertion of friends, and the scorn of society. *Physical pain* is much less frequently a cause of suicide, than moral suffering. Many, however, of the ancient Stoics put an end to pain by terminating their lives, — thereby following the example of ZENO, the founder of their sect; and several Romans have been mentioned by PLINY and others, as having adopted this course. Dr. HASLAM states, that a gentleman destroyed himself to escape from the tortures of gout. I have been told by several persons that, whilst suffering the pangs of neuralgia, it required the utmost efforts of their moral principles to restrain them from perpetrating self-murder. Numerous instances are on record, of persons who, having believed themselves suffering incurable maladies, have had recourse to suicide, as a more pleasant mode of dying; this crime being committed by them under the impression that a natural death is more painful than that inflicted by themselves. It has, however, been long known, and shown by HUFELAND and W. PHILIP, that death from disease, even when the mental faculties are retained to nearly the last, is attended by a gradual abolition of the general sensibility that is by no means painful or distressing; the patient ceasing to exist as happily and calmly as when falling asleep, unless under peculiar circumstances.

584. *l.* Suicide is often committed in *states of irritation and chagrin*, particularly by persons of a morose, splenetic, or irritable temper. It is sometimes suggested to such persons by a desire to excite regrets or self-reproach in the minds of those who have offended them, — by a feeling of *revenge*. Most of the suicides committed by *children* are caused by a desire of this kind; particularly when they follow punishment of any description. Self-murder arising from *jealousy*, also, depends chiefly upon the promptings of this feeling, in connection with anger; and is most apt to occur in *hysterical*, *nervous*, or *weak-minded females*. Some years ago, I was present at an evening party, where a young lady, engaged to a gentleman present, was seized with hysterical convulsions, in consequence of his attention to another. Upon recovering from them, she suddenly left the house, without the direction she took being observed. The following day she was taken out of the Canal near the Regent's Park, in her ball-dress, — she having gone upwards of a mile in order to carry her design into execution. A lady, on a similar occasion, took a large quantity of laudanum. The usual means of restoration producing no effect, I was sent for: she was ultimately recovered by the affusion of cold water on the head.

585. *Domestic contrarieties* and *misery* — the frequent recurrence of petty vexations — the tyranny of intimate connections, and the positive ill-usage of others — suits in courts miscalled those of *equity*, on the *lucus a non lucendo* principle — may, from their continuance, severity, and repetition, especially under aggravating circumstances, and in states of high susceptibility in the unhappy sufferer, drive even the strong-minded and the well-principled into a state of temporary despair or desperation — may fire the brain to madness, during which self-destruction may be attempted. A most talented and accomplished young lady, suffering from a combination of the above circumstances, took, upon retiring to rest, and with a suicidal intention, a very large quantity of laudanum, — more than is usually productive of a fatal effect. She wakened late the following day, with a most distracting headach and general disorder, recollected the act of the previous night, regretted the attempt, and sent for medical aid — determined, however, to conceal the cause. Her health, from this and the other circumstances alluded to, continued greatly impaired for many years, and several physicians were consulted. She came under my care, and at last mentioned the suicidal attempt, which was never further divulged. She now continues, in good health, to ornament the society in which she moves. M. FALRET mentions, among other causes of chagrin producing suicide, that of having been calumniated; and he states, that a considerable number of persons commit this act chiefly with a desire of vindicating their reputation, — no other means of vindication being in their power.

586. The *state of desperation*, into which a person influenced by the *passion of love* may be thrown by disappointment, is actually that of insanity — at least, of moral insanity. A gentleman endeavoured to obtain the favourable notice of a lady, of whom he had become enamoured, but had not succeeded. He committed suicide by opening a vein in his arm, and, whilst the blood was flowing, he wrote a note with it, acquainting her with his act. She was soon after attacked by nervous fever, which was followed by insanity, during which she fancied that she heard a voice commanding her to commit suicide. Other instances of a similar kind may be adduced.

587. Some persons, during *intoxication*, have a remarkable disposition to commit self-murder. This disposition may be the consequence of either habitual or occasional intoxication; and it is sometimes connected with *delirium tremens*, or, rather, depending upon the illusions attending that disease. Some persons, who have received, at a former period of their lives, severe injuries of the head, experience this disposition, when even but slightly affected, in other respects, by intoxicating liquors — especially if they suffer any contrariety or opposition at this time. Cases of this kind have been noticed by M. FALRET, and others, and by the author.

584. *m.* Instances of *mutual or associated suicide* are not rare, particularly in recent times. The self-homicides of LUCIUS VETUS, SEXTIA, and POLLUTIA, during the reign of NERO, and of SARDANAPALUS, may be noticed amongst the many instances recorded in ancient history. During the French revolution, and the wars consequent upon it, associated suicides were frequent. Nine conscripts who had concealed themselves, having been discovered, determined to destroy themselves rather than serve: they drowned themselves together. The most common causes of this mutual crime are, opposition on the parts of parents to the fulfilment of marriage engagements entered into by young persons, want or disappointments in the married state, and family dishonour. The bodies of two young persons were found in

the Seine, with a piece of paper attached to them, testifying to their ardent affection, and that they perished together that they might be eternally united. Occurrences of this kind are, however, not unfrequent in this and other civilised countries; and instances are not rare of lovers committing mutual suicide, even where there was no opposition to the consummation of their wishes. In this latter case, some cause of chagrin or disappointment has occurred, and maddened the mind already disordered by one dominant passion, — the suicidal intention entertained by either being adopted by the other. From the accounts of several cases of mutual suicide attempted in recent times, there is every reason to suppose that the attempt was merely *simulated* by one of the persons who had agreed to commit this crime; and that it had been contrived entirely with the intention of getting rid of an object no longer one of endearment. This is more likely to be the case, when a young woman has become pregnant by one of those drunken debased workmen who prey upon females in large or manufacturing towns. This and similar instances have appeared in the public prints. A man out of work, and his paramour, having agreed to commit mutual suicide, procured some laudanum (about four ounces), and divided it into two equal quantities. The man proposed that they should turn back to back whilst taking it, in order that they might not falter in the act. The female died soon after; but the man did not appear to be affected. From the evidence at the inquest, it did not appear that he had actually entertained an intention to destroy himself, or had taken any of the laudanum. Analogous cases have occurred, where drowning has been the mode of carrying the suicidal act into effect; one of the parties having escaped.

589. Want and other causes of distress, and even more petty grievances, may, in states of mind but little influenced by moral and religious principles, induce husband and wife to commit mutual suicide. In the present state of society, especially in Paris, where the passions are roused and excessively gratified before reason and judgment are informed — where sensibility is exhausted at an early age, by the excitement of sensations, in great variety, in rapid succession, and increasing intensity — where the thirst for pleasure is promoted by a loose and stimulating literature — and where the end of enjoyment is generally shown, in the pages of the novelist and in the scenes of the dramatist, to be murder and suicide, — instances of associated self-destruction, even among persons in no way dependent upon each other, have not been rare. Young men, who have exhausted either the means or the power of enjoyment, or both, in the career of vicious indulgence, and unrestrained by principle and by fear, have followed the example held out to them by the popular writers of the day, and "shuffled off this mortal coil" in the most dramatic forms they could devise. Two young men entered a *restaurant*; ordered an expensive dinner, with costly wines, without the intention or the means of paying for it; and soon afterwards committed suicide together. On a table in their room were found written papers, expressing aspirations after greatness without either labour or care, and contempt for those who could live by their own exertions, with sundry quotations from Victor Hugo and other exciting writers of the day. The whole was terminated by a request that their names and the manner of their deaths might be sent to the newspapers! Sensation is the object and end of living, with many, in the present day; and when it can no longer be excited, — at least, to the pitch, or in the tone, capable of yielding enjoyment, — life is relinquished in such a way as is most likely to excite the sensations of others.

590. *n.* *Murder* is often committed first, and *suicide* afterwards, prompted by the same or different motives. — *Jealousy* is one of the most frequent causes of this combination of crimes, which, however, may be prompted by a variety of circumstances, — indeed, by all which occasion suicide or insanity. The following instances are fully detailed by Mr. Winslow: — M. De Pontalba, whose son was a most distinguished officer, and married to a most extravagant woman, saw with distress the ruin she was bringing upon him. In order to save the son, the father shot the daughter-in-law, and afterwards himself. — A gentleman of London was married in the country to the object of his affections. He had drawn the charge from his pistols the previous night, but his servant had loaded them again the following morning without acquainting him. After the ceremony he took up one of the pistols, which he knew he had unloaded the night before, and playfully rallied the lady on her cruelty, saying, "You shall die, you tyrant! you shall die with all those instruments of death about you — with that enchanting smile, those killing ringlets of your hair?" — "Fire!" said she, laughing. He pulled the trigger, and she was shot dead. He called up the servant, and, upon his entering, locked the door, and inquired if he had loaded the pistols? "Yes," was answered; on which his master shot him with the undischarged pistol. He wrote * to his wife's father, explaining the calamity, and then threw himself upon his sword.

591. Instances are not rare, of a parent or parents, influenced either by want, or by homocidal monomonia, killing their children, and then committing suicide. Although extreme wretchedness is sometimes the chief occasion of these occurrences, yet it is seldom the only occasion. More frequently some form of partial insanity is either the principal or concurring cause; some circumstance having occurred to excite the homocidal propensity. Dr. Gall mentions the case of a soldier, of whose wife an officer had become enamoured without succeeding in his wishes. The soldier appeared dejected and morose, but the following day appeared quite tranquil. A few days afterwards, he and his wife attended the confessional and took

---

* The letter will show the state of mind produced by causing the death of a much-loved object, particularly as leading to suicide. This gentleman had written immediately upon the performance of the ceremony, and had concluded the note as follows: — "The bride gives her duty, and is as handsome as an angel. I am the happiest man breathing." This soon afterwards was written: — "Two hours ago, I told you truly that I was the happiest man alive. Your daughter lies dead at my feet, killed by my own hand, through a mistake of my man's charging my pistols unknown to me! I have murdered him for it. Such is my wedding-day. I will follow my wife to her grave: but before I throw myself upon my sword, I command my distraction, so far as to explain my story to you. I fear that my heart will not keep together till I have stabbed it. Poor good old man, remember that he who killed your daughter, died for it! In death, I give you thanks, and pray for you, though I dare not pray for myself. If it be possible, do not curse me. Farewell for ever!

the sacrament; they dined in good spirits, and went out to walk; he expressed his strong affection for her, and inquired if she had made a full confession to the priest. He then plunged a poniard in her breast. He repaired to his house, and seizing his children, killed them with a hatchet. He afterwards went to the main-guard, and deliberately detailed the whole particulars, concluding with the words — "Let the officer now make love to my wife, if he pleases!" He then stabbed himself to the heart.

592. *o.* Suicide is often *simulated*, with a view of obtaining a desired end; — the lover threatens or seems to attempt it, to induce a return of his affection; the spoilt child, to obtain a compliance with his wishes; and the indulged wife, submission to her caprices. In such cases, either a small portion of laudanum is usually procured, and this is diluted with some fluid, to increase the apparent quantity; or a large quantity is taken, when seen by some person, or when instant aid may be obtained. Females have resorted to this plan, to try the affection, or to compel the fulfilment of the engagements, of their lovers; but, in cases of this kind, little more is necessary to be known, than that such acts are sometimes resorted to; and that a poisonous dose may be actually taken, in order to appear the more in earnest, knowing that assistance is near, and that it will be successfully employed. Drowning even may be feigned in similar circumstances. I have, however, seen two cases, in which fatal results very nearly followed this experiment upon the endurance of affection.

593. *B. Predisponent circumstances.* — Besides the above *exciting* occasions of suicide, others, which powerfully *predispose* the mind to their influence, and to which attention has been imperfectly directed, require to be briefly noticed, — namely, *hereditary predisposition; systems of philosophy and of morals; states of education, of manners, and of society; distracting subjects and studies; irritation caused by difficult and perplexing circumstances; injuries of the head, and physical disease; the influence of climate, of seasons, weather, and states of the air on the nervous system, and of age, sex, and temperament*, &c.

594. *a.* The influence of *hereditary predisposition* in occasioning suicide, is well established. In a very large proportion of instances, either self-murder has been perpetrated by one of the older members of the family, or some form or other of insanity has appeared in one or more of them. Very frequently, one or both parents of the suicide have been noted for eccentricity, or the waywardness, instability, or violence of their dispositions and tempers. Instances have occurred, of the children of a parent who has committed self-destruction, perpetrating the same act when they have grown up, or at later periods of their existence. Even more than one — several — of the offspring have experienced this fatal disposition upon arriving at nearly the same epoch of life as that at which it was committed by their parent. Dr. Gall has observed the suicidal predisposition in several successive generations. I have known it in three generations. M. Falret considers suicide to be more intimately dependent upon hereditary predisposition, than any other form of insanity; but this is chiefly the case in respect of suicide connected with melancholia and other forms of partial insanity.

595. *b.* The influence of *systems of philosophy and of morals*, in increasing the frequency of suicide, is undoubted. The doctrines of Zeno and Epicurus encouraged it among the ancients. Since the revival of learning, Montaigne was one of the earliest and ablest of those who favoured the perpetration of this act, but all his arguments are derived from the ancient Stoics. The early writings of Dr. Donne seemed to favour suicide; but they actually go no further than to show, that contempt for, or even the sacrifice of, life is praiseworthy in the discharge of our duties, and in the execution of beneficent and noble undertakings. The reasonings of Hume, and the indirect support which the doctrine they favour received from the writings of Montesquieu, of Rousseau, of Göthe, De Staël, and others, probably contributed less, than is supposed, to the increase of this crime. It is, however, not to be disputed, that the loose principles disseminated, and the violent feelings displayed and exerted, by the warm and passionate writings of Rousseau and Göthe, promoted this end much more than the metaphysical and moral arguments urged in favour of it. Madame De Staël has stated that the *Sorrows of Werter* caused more suicides, at one time, in Germany, than all other circumstances combined. Whatever of mischief has arisen in this direction from modern writings, has been indirect — has proceeded chiefly from the injurious influence exerted upon the mind by an exciting, profligate, and debauching literature, for which the state of society and manners has procured a very extensive circulation; and not so much from the arguments adduced by a few metaphysical writers of more confined, although more lasting, reputations. The poison instilled, continually and in wide profusion, into the minds of all classes of the community, through the media of the numerous works of passion and imagination with which the presses of the civilised world at present labour; the taste for their perusal, which numerous circumstances of the times conspire to diffuse; and the moral contamination which they spread, or render still more deep and malignant, most sensibly dispose the mind to suicidal impulses, when subjected to the exciting causes already noticed. That the doctrine of *Materialism*, however, and the general scepticism to which it leads, disposes the mind to suicide, inasmuch as it weakens the belief of a future state of rewards and punishments, cannot be disputed. The *infidelity* so widely diffused towards the close of the last century, by means of the sceptical writings of that, and of a somewhat earlier, period, doubtless, contributed to the frequency of suicide, especially in France, during that eventful epoch; and there is every reason to believe that its influence is still exerted, although to a somewhat less extent than then.

596. *c. Education and states of manners and of society* may be such as to favour, or to counteract, a tendency to self-murder. If *education* be conducted without regard to religious and moral principles — if the knowledge of words, of things, of facts, and of phenomena, be made to supersede sound principles of conduct, and of belief — if the amount of knowledge communicated, rise above, or reach beyond, the sphere of utility and of enjoyment — if, in short, education be conducted in the manner in which I have already shown it (§ 271, 272.) to be generally conducted

in the present day, — it will tend much more to increase the number of our wants, to develope our desires and passions, to augment their intensity and violence, at the same time that it removes from them those salutary restraints which prevent them from becoming dangerous to others or destructive to ourselves. The influence of education thus loosely conducted, upon the *pseudo-liberal* principle of rendering it acceptable to all creeds, — to the Churchman, the Romanist, the Presbyter, the Baptist, the Socinian, and all other persuasions — "to Christian, Turk, and Jew" — proves injurious, not only in the way just stated, but also in giving rise to forced, unnatural, over-reaching, ambitious, and unprincipled states of society; and these states, in proportion as they are developed, are the parents of crime, insanity, and suicide. Throughout the community, and particularly in the middle classes, there is a constant effort to rise above the ranks which Providence has assigned; and to partake of the pleasures and luxuries which are far beyond the means of some, and are conducive to libertinism and profligacy in many of those who enjoy them the most. The end of excessive indulgences, and of debauchery in every form, particularly when early pursued, is suicide or insanity, or the unequivocal combination of both, in many instances.

597. There can be no doubt of the pernicious principles recently inculcated, particularly amongst the lower orders of society, and to which the name of *Socialism* has been given, having already conduced, in several cases, to suicide. This doctrine, inasmuch as it unlooses the ties of society and of consanguinity, as it admits of no moral responsibility, and as it allows no expectations of future rewards and punishments, is opposed to all moral and religious obligations, — it favours vice and profligacy, overthrows all virtuous and salutary restraints upon the feelings, and, by allowing without control the indulgence of the desires and passions, favours what has just been shown to be the ultimate consequences of this course. In this state of society, the endearments of friends, of connections, and even of relations, cease to exist. The ties which bind society together in harmony, are broken asunder; and as soon as the race of selfish indulgence is run, — as the power of enjoyment is exhausted,—the mind, having no affections, no friendships, no self-consoling and truly gratifying recollections to repose upon, at once sinks into a state of abject wretchedness, which it seeks to terminate by self-murder.

598. In illustration of what I have stated, I may adduce what has been advanced by a French writer, in accounting for the frequency of suicide. This writer remarks, that the high civilisation and refinement, the luxury, the clash of interests, the repeated political changes, combine to keep the moral feelings of the Parisians in a state of tension. Life does not roll on in a peaceful and steady current, but rushes onwards with the force and precipitation of a torrent. In the terrible struggle, it often happens that the small minority, which has been elevated high above the multitude for a time, falls down as suddenly as it has risen. The drama of life is full of miscalculations, disappointments, disgust, and despair: hence the numerous suicides. But there are other causes in operation,—and not the least, the remarkable character which romances, plays, and spectacles have assumed. The public taste has undergone a complete revolution in this respect. Nothing is more patronised now at the theatre, than the display of crime unpunished, human misery unconsoled; and a low literature, impregnated by a spurious philosophy, declaiming against society, against domestic life, against virtue itself; applauding the vengeance of the assassin; and recognising genius only as it is seen in company with spleen, poison, and pistols. This writer concludes with appealing to those who read the novels of the present day, and who visit the theatres, whether he has exaggerated his statement; and I may appeal to all in this country, who are acquainted, not only with the state of our popular literature, and of the stage, but also with the character of the daily, weekly, and even monthly publications, which are hourly devoured by all classes — with their natures and contents, — whether this writer has not underestimated the influence of these causes.

599. *d. Harassing subjects and abstract studies*, especially when undertaken by minds which have undergone an imperfect preliminary course of information and discipline, sometimes occasion so much distraction as to give rise to suicide or some form of insanity. Several instances of suicide have occurred from the pursuit of subjects too abstract either in themselves, or in relation to the power of the individual's mind. In such cases, an extreme state of irritability of temper is often evinced before the suicidal act is attempted. Indeed, the irritation produced by any difficult and perplexing circumstance, as well as by great losses and disappointments, is very apt to terminate itself in self-murder, when experienced by the weak, the indulged, the fortunate, or the undecided and wavering mind. In the present general scramble for wealth, often merely for existence, and as often only to obtain the means of retaining a position falsely usurped, or too sanguinely entered upon, the irritation and distraction which often necessarily result, not infrequently lead on to suicide. The rich man gambles in the funds, foreign or domestic, or in joint-stock shares, or in the prices of foreign and domestic produce, in order to double by a single speculation, what he had slowly acquired by prudence or application. The poor man places his last or only stake, and his own and his family's happiness, upon a contingency not more secure than the hazard of a die. In either case, adverse fortune brings distraction, which reason is not always able to calm. A gentleman, who had acquired a large fortune by a long life of prudent application to business, ventured the greatest part of it in the foreign funds: he might, at one time, have sold with great advantage: but they fell rapidly; and, under the contemplated loss of 70,000*l.*, he terminated his existence. Another, similarly circumstanced, went repeatedly with the intention of selling at a time when he might have gained many thousands. His want of decision prevented him on each occasion from carrying his design into execution: the period of extricating himself had passed; and, in a state of irritation at his loss, and at his wavering state of mind, he committed suicide. But such occurrences almost daily take place; for trading and commercial transactions very generally possess, in the present day, very much of the same gambling character. Even the small capitalist is desirous of investing, or of speculating with, the

savings of years, in some one or other of the numerous schemes, promising large returns, concocted by those who are well aware of the existing passion for gain, and who know well how to turn it to their own advantage, but to the loss, misery, and destruction of their dupes, many of whom, in a state of distraction occasioned by their ruin, commit suicide.

600. *e. Injuries of the head, and physical disease,* sometimes either predispose, or directly give occasion, to suicide.—*Injuries* received at a remote period may give rise to it, without having previously excited any marked state of disease, or even mental disorder; and yet, upon examination after death, lesions of structure have been, in some instances, detected, either in the brain or its membranes, or even in both. More frequently, however, physical disease, often slight, but still manifest, shows itself; or some degree of mental disorder, or some illusion, is evinced, of which the suicidal impulse is only a symptom or a concomitant. In most cases, the injury which originated the mischief, has been so slight as to be considered unimportant by both the patient and his friends.

601. *Visceral disease* has a similar influence in causing suicide, as I have shown it above (§ 309. *et seq.*) to exert in producing insanity. When the abdominal viscera, particularly the digestive organs, are chiefly in fault, hypochondriasis and melancholia are first developed; the disorder of these organs acting upon, or disordering the circulation in, the brain. When the intention or the impulse to commit self-murder originates in primary disease of the brain itself, some form of monomania, or of mania, generally either precedes, or attends it. In most cases of suicide arising from visceral disease, either organic nervous energy has been remarkably depressed by exhausting causes, as by masturbation, drunkenness, and libertinism; or this disease has been only an accidental or concurring cause,—one or more of the circumstances or occasions already noticed having been more or less concerned in producing the suicidal determination.

602. *f. Seasons, weather, and climate* have been generally supposed to exert some influence in disposing to suicide. M. VILLENEUVE considers that a warm, cloudy, and humid state of the air increased the number of suicides in Paris, Marseilles, and Rouen; and that stormy weather seemed to exert a similar influence. The effect of warm and humid states of the air upon the nervous system is often very manifest, in depressing its energies, in weakening the mental powers, and in lowering the spirits. The greatest number of suicides has been said to occur when the thermometer ranges above 75°. Dr. BURROWS observes, that, on examining the tables kept at Westminster from 1812 to 1821 inclusive, and at Hamburgh from 1816 to 1822 inclusive, the number of suicides in both cities was greatest in July, and least in October. A similar result has been remarked in respect of Rouen and Copenhagen. From 1817 to 1826, the number of suicides committed in Paris amounted to 3205; of which 997 were perpetrated in spring, 933 in summer, 627 in autumn, and 648 in winter; the following being the numbers with reference to the months:—January, 213; February, 218; March, 275; April, 374; May, 328; June, 336; July, 301; August, 296; September, 248; October, 198; November, 131; December, 217.—November has been said to occasion greater despondency and despair, and more suicides, than any other month; yet this month, both in London and in Paris, presents the smallest number of self-murders, with the exception of October. Notwithstanding the influence of warmth and humidity of atmosphere, in increasing the number of suicides, this act is much more common in the colder than in the warmer countries of Europe;—France, Germany, England, and Denmark, being the kingdoms in which it is most frequently committed. In the summer of 1806, 60 cases took place in Rouen, and nearly 300 in Copenhagen; the weather being warm and moist. In Berlin, 500 instances occurred in six years and a half; whilst at Naples there was, in 1826, only 7, in a population of 349,000; and in all Spain, in the same year, there were only 16 cases. Dr. KAMPTZ, of Berlin, has assigned the proportion which suicides bore to the population, in several places in Europe, for the year 1817. I abstract only a few cities:—

Berlin	57	suicides,	166,584	popul.,	or 0,34 in 1000.
Breslau	58	—	63,020	—	or 0,92 in 1000.
Magdeburgh	50	—	27,869	—	or 1,79 in 1000.
Copenhagen	51	—	84,000	—	or 0,60 in 1000.
Paris	300	—	700,000	—	or 0,42 in 1000.
London	200	—	100,000,000	—	or 0,20 in 1000.

No just inference, however, can be drawn from returns of the suicides committed during one year only, in different climates or countries; as several circumstances, either uncommon or fortuitous, may have occurred, in one or more of these climates, at that period, to increase or diminish the usual numbers,—as great prosperity or adversity, plenty or scarcity, political commotions or revolutions, &c.— Nor is it to *climate* or *season* that much influence is to be imputed in occasioning suicide; but chiefly to the various circumstances already noticed, in connection with religion, commercial speculation, and states of society. It is sufficiently established, however, that, throughout the most of Europe, and in the United States of America, suicides have become much more frequent than at the above, or at almost any preceding, period, unless during the French revolution. The number has increased in Paris from 300 in 1817, to 511 in 1826; and in Copenhagen, from 209 during 1790, and the four successive years, to 319 during the first five of the nineteenth century.

603. The admitted increase of suicides, more especially in this country, is not to be altogether referred to the more general influence of the several occasions already mentioned; but in a great measure, also, to the increased numbers and circulation of those prints, which abound with the disgusting details of profligacy, crime, and suicide. Dr. BURROWS justly remarks, "that the public taste has become more and more vitiated and debased by this species of gratification; and nothing is found so attractive as tales of horror and of wonder; every inquest that is held upon a person who has destroyed himself, being read with great avidity." The ludicrous police reports of criminal acts furnished by the daily panderers to our more debased desires, scenic representations of successful vice and crime, and the constant circulation of suicidal acts in all the periodical prints, serve most essentially to familiarise the minds of the lower classes especially, with these acts, and to diminish

the detestation with which they are generally viewed at first, until the moral sensibility becomes altogether blunted by their perusal. The repeated presentations of these crimes to the minds of the ignorant and vicious,— often not only divested of their attendant horrors, but even clothed in attractive garbs, — readily suggest a recourse to them, in circumstances which cause distress, irritation, or distraction. Literature — if, indeed, the trash vomited hourly from the steam press should be dignified with the name — has become the most debased of modern ways of traffic ; and its chief end, in the present day, is to encourage those feelings and desires, by means of which its diffusion and profitable returns may be augmented. In order that this may be the more surely effected, and with the greatest amount of moral contamination to the community, and of pecuniary profit to the writers and proprietors, — that the criminal appetite may be pampered and increased — that each successive meal of criminal indulgence may be followed by a greater relish, and a more craving desire for its repetition, — foreign countries are ransacked to furnish what our own cannot supply in sufficient frequency and piquancy.

604. *g. Age and Sex.*—The frequency of suicide varies at different *ages*. During the early epochs of existence, the sanguine expectations, which are generally indulged, and which soon take the place of temporary despondency and distraction occasioned by disappointments and losses, tend to diminish the number of suicides. In the middle and more advanced periods of life, sensibility becomes exhausted or blunted, whilst cares and anxieties increase in number and intensity ; and the attachment to life is much impaired. The desire of life afterwards increases, and frequently in proportion as old age advances. M. Falret has shown, that it is from 35 to 45 that the greatest number of suicides occur. Of 6782 cases, 678 were under 20 years of age ; and of this number, 487 were between 15 and 20, and 181 below the age of 15. A child of nine years old * wished to destroy itself ; but this is the only case of so early an age. After 45, suicide becomes more and more rare ; and above 70, there are scarcely any instances of it. The father, however, of the celebrated Barthez killed himself at the age of 90 ; and his son, when he was old, wished to follow his example.

605. Both *sexes* display the suicidal tendency, but the male sex most frequently. M. Esquirol considers the proportion of males to females to be 3 to 1 ; but there are differences according to countries, arising from the greater or less influence of many of the circumstances shown to favour this act. Thus, in France, there are more suicides among women than in Germany. It has been observed, both in England and on the Continent, that nearly two thirds of suicides were unmarried. This state, therefore, is much more favourable to self-destruction than the married condition.

606. *h.* Suicides are most frequent among persons of the *melancholic temperament* and *bilious constitution*, with a pale or sallow, or yellowish complexion, and hard or sharp features. Such persons are more liable than others to disorders of the biliary and digestive organs. But this crime is not infrequently committed by the nervous and irritable, and even by the sanguine and plethoric. Females of this latter constitution occasionally attempt or perpetrate self-murder, just before or during the catamenia, or from some irregularity of this evacuation. M. Esquirol states, that the *scrofulous diathesis* is remarkable in a number of suicides.

607. *i.* Several *tables*, showing the frequency of the several *causes* of suicide, have been published ; but are obviously deficient in precision, as well as in the truth of the data upon which they are based. Moreover, this act is not generally prompted by a single circumstance, or cause, only ; but by the combination, concurrence, or succession of several. With great allowances, and reservation, the following may be adduced, in the absence of more accurate information, as to the comparative influence of the circumstances occasioning this crime. The suicides committed in London, between the years 1770 and 1830, have been stated (*London Med. and Surg. Journ.* vol. v. p. 51.) to be 4337 men, and 2853 women ; and the causes have been thus assigned : —

Causes.	*Men.*	*Women.*
Poverty	905	511
Domestic grief	728	524
Reverses of fortune	322	283
Drunkenness and misconduct	287	208
Gambling	155	141
Dishonour and calumny	125	95
Disappointed ambition	122	410
Grief from love	97	157
Envy and jealousy	94	53
Wounded self-love	53	53
Remorse	49	37
Fanaticism	16	1
Misanthropy	3	3
Cases unknown	1381	377

According to M. Falret, of 6782 suicides committed between 1797 and 1823, 254 were from disappointed love—157 being in women ; 92, from jealousy ; 125, from the chagrin caused by calumny ; 49, from a desire, without the power, of vindicating character ; 122, from disappointed ambition ; 322, from reverses of fortune ; 16, from wounded vanity ; 155, from gambling ; 287, from crime and remorse ; 728, from domestic distress ; 905, from poverty ; 16, from fanaticism. Upon comparing this table with the preceding, very great inaccuracy will be apparent, — proving the very little dependence to be placed upon numbers in medical details. Of 500 suicides, committed in Berlin, during six years and a half, Dr. Caspar states that 14 were caused by offended honour ; 61, by insanity ; 54, by drunkenness and dissipation ; 32, by dread of punishment ; 18, by debt and domestic trouble ; 12, by love ; 11, by matrimonial strife ; 3, by disgust of life ; 12, by disease and pain ; 1, by religious excitement ; and 282, by causes which were not specified.

608. *C.* The *modes selected of quitting life* may be briefly noticed. These, in many instances, have some reference to the occupation or profession of the suicide. Thus, military and naval men shoot themselves ; chemists and medical men poison themselves, chiefly with prussic acid ; barbers and hairdressers cut their throats ; shoemakers stab themselves, &c. — Fire-arms and sharp instruments, particularly pistols, razors, knives, and daggers, are most frequently employed by men. Drowning, hanging, poison, and precipitation

---

* I am now attending, for a physical ailment, a boy of 12 years of age, who attempted suicide by hanging, from a feeling of revenge for being punished.

from windows or great heights, are the means of self-murder most commonly resorted to by women. In France, asphyxy, by the vapour of burning charcoal, is often selected by females, and even by males — particularly in cases of associated suicide. Hanging, drowning, and poison are, however, the means most frequently resorted to by both sexes. The choice thus made, does not always depend upon what may be supposed to cause the easiest or the most rapid death; but, probably, upon that mode which offers the greatest facility, or is the most readily carried into effect in moments of irritation, distraction, or depression. It is remarked, that a very large proportion of suicides by drowning, in London, are committed by persons residing in the vicinity of the river, and of the Regent's Canal.

609. Dr. Caspar states, that of the 525 cases of suicide already noticed, 234 were committed by hanging; 163, by shooting; 60, by drowning; 17, by cutting their throats; 20, by stabbing; 19, by throwing themselves from windows; 10, by poison; 2, by opening an artery. M. Esquirol gives the following details of 205 cases of suicide in *females:* — 49, by hanging and strangulation; 45, by precipitation from windows, &c.; 2, by firearms; 18, by sharp instruments; 7, by poison*; 5, by asphyxy; 48, by starvation; 31, by drowning.

610. ii. Arrangement of the Causes of Suicide. — *A. Circumstances predisposing to this act.*— Hereditary predisposition; the melancholic, bilious, and irritable temperaments; the middle period of life; the male sex; the unmarried state; indulgent and injudicious education, without reference to moral and religious principles; masturbation and sexual excesses; drunkenness; immoral amusements and exhibitions; the perusal of loose productions, and of criminal and suicidal details; idleness and indolence; habitual recourse to powerful mental excitement; infidelity, or a disbelief of a future state of rewards and punishments; states of the air, or of the season or weather, occasioning depression of the nervous energy.

611. *B. Circumstances exciting this act, or occasional exciting causes.* — *a. Direct occasional causes.* —The passions and feelings, — particularly love, conjugal affection, jealousy, ambition, humiliated pride, sentiments of dishonour, loss of female virtue, feelings of shame, violent anger, fear, terror, and remorse; gambling, either from want, or a desire of strong emotion and excitement, or covetousness; imitation, or mental infection; fascination on looking down from precipices; chagrin, desperation or distraction; reverses of fortune; disappointments, domestic unhappiness, and family dissensions; the several forms of moral and partial insanity, especially melancholia and religious insanity; the different states of general insanity, particularly mania and puerperal insanity; and the delirium consequent upon numerous physical maladies.

612. *b. Indirect occasional causes.* — Bodily diseases of various kinds; violent pain, and incurable maladies; the abuse of intoxicating liquors, of opium, of mercury; distaste of life connected with the change of life in females, and the loss of attractions from small-pox, &c.; ennui, or tædium vitæ, consequent upon an effeminate and indolent state of existence, or a state of mind in which the passions are without an object to excite interest, or are incapable of being roused to feel an interest; want and its attendant miseries; anticipated exposure or punishment; motives of revenge.

613. *c. General causes.* — Governments which furnish numerous examples of violent deaths, in the execution of their laws, or which possess a sanguinary penal code; the military spirit, and military governments; republican and democratic constitutions; political commotions, revolutions, and catastrophes — especially at their breaking out, or after the state of excitation and turbulence has passed away; religious fanaticism, and still more the want of religion; superstitious doctrines; unsound religious and philosophical opinions; depraved states of society, of manners, and customs.

614. *C. Causes most influential in this and other free and commercial countries.* — The range given to the social passions; the hazards and losses in mercantile speculations in the funds, and in joint-stock speculations and companies, and the consequent ruin and debasement of families; habits of dissipation, the indolence and ennui consequent upon wealth and sated enjoyment; the importance attached to public opinion, and the instability of that opinion; the violent shocks and collisions of opposing parties; the inactivity to which military and naval persons are reduced during times of peace; the enthusiasm of religious and philosophical sects; the immorality of the literature and scenic representations of the age; and the details of crime and of suicide, which constitute a principal part of the daily reading of all classes of the community.

615. iii. Pathology.—*A. The lesions observed in suicides upon dissection.* — These, in many cases, will necessarily be the same as have been already described in cases of manifest or fully developed insanity. In many instances, the lesions will have no reference to the production of this act; and, in some, they will be merely the consequences of previous disease, which had nothing to do with the subsequent occurrence of a suicidal impulse. The physical disease may have, in some cases, predisposed to the indulgence of a suicidal intention, by weakening the vital manifestations, and particularly the powers of mind; but, even in such cases, the mental emotion is to be looked upon as the efficient cause of the act. Without, however, attaching much importance to the influence of the structural alterations in producing it, as far as they have been yet investigated, unless when it is unequivocally dependent upon insanity, I shall briefly state those which have been most frequently noticed. Heister observed lesions of the liver, gall-bladder, and pancreas. Falret considers alterations of the liver to be rare; M. Esquirol remarked displacement of the colon; Osiander, congestion of the vessels of the brain, and chronic inflammation of the intestines; Corvisart, Alberti, and Osiander, diseases of the heart; Greding and Gall, thickening and condensation of the cranial bones; Home, dilatation of the sinuses of the dura mater, and effusion of serum in the ventricles, and between the membranes; Recamier and others, thickening of

---

* The small number of suicides by poison, in the tables furnished by Caspar and Esquirol, deserves remark. On the Continent, it is very difficult to procure poisonous substances unless by means of a physician's prescription. In this country, a child or any wretch may procure them for purposes of murder or suicide, without any difficulty and at the lowest prices, at all the shops with very few exceptions where drugs and medicines are vended.

the arachnoid and dura mater, with ossific depositions in the latter; Falret and Foville, traces of vascular irritation and excitement in the membranes and substance of the brain; and Frank and Esquirol have failed, in many instances, to detect any appreciable lesion of any organ. From 1333 inspections of suicides, the following results have been given, but with little appearance of precision or accuracy: — Thickening of the cranial bones in 150; bony excrescences from their inner surface in 50; disease of the membranes of the brain in 170; inflammatory appearances of the brain in 90; simple congestion of the brain in 300; tumours in the brain in 10; softening of the brain in 100; disease of the lungs in 100; lesions of the heart in 10; disease of the stomach in 100; alterations of the liver in 80; lesions of the intestines in 50; suppression of the natural secretions in 15; syphilitic disease in 8; and no apparent structural change in 100. (See § 223. *et seq.*)

616. B. *Physiological Pathology.* — Suicide may be viewed, in many cases, even when proceeding from passion and feeling, as the result of deranged action of the vessels of the encephalon and of its membranes, consequent upon altered sensation or excited emotion; but it cannot be considered as essentially and exclusively depending upon this pathological cause. The intellectual and moral phenomena, which either directly or indirectly give rise to the suicidal determination, cannot be shown to be always the consequence of vascular lesion, or even of excited vascular action; although they often lead to such lesion, from the intimate connection existing between the mental manifestations and the organic actions. The numerous instances in which suicide is attempted, from ebullitions of temper or gusts of passion or feeling, and in which the means of self-destruction fail of accomplishing the intended end, leaving those who made the attempt calm, resigned, and happy at having failed in their intentions, fully prove the absence of established vascular lesion; and show the remarkable difference between these and cases depending upon real and confirmed insanity, which we never find so immediately and permanently cured, as those instances of attempted suicide fortunately are, and cured by the same means as so generally fail in every form of suicide proceeding from manifest insanity, wherein, it may be presumed, that lesion of vascular action in the encephalon, as well as of organic nervous power, actually exists. We are therefore obliged to conclude, that mental power may be, *hereditarily* or *originally*, or from the influence of the *predisposing causes* of suicide, so weak, or so morbidly impressible or susceptible, as to give way to the impulses to this act, arising out of any of its exciting causes, either before the controlling powers of mind have had time to re-act and to resist the suicidal impulse, or from the circumstance of those powers having been so weakened as to be incapable of sufficiently resisting this impulse when excited by powerful or by combined causes. In these cases, this act is to be imputed to the state of mental energy — to a constitution of the mind arising out of hereditary conformation, and the prolonged operation of predisposing circumstances, rather than to any appreciable disorder of the cerebral circulation.

617. On the other hand, it ought to be admitted, that incessant application to study, to business, to political events, to the views and interests of parties and sects, to the discharge of public duties, or to the support of public measures, as well as many of the numerous causes above specified, will so far overturn the equilibrium of the circulation, as to occasion an erethism of the vessels of the brain and its membranes, verging upon inflammation, if not actually amounting to it. Such a condition of this organ may betray itself by a slight delirium, or partial or slight form of mental alienation, by general irritation or nervousness, or by slight fever, or by burning headach, with little other disturbance of the system; or it may evince itself by a peculiarity of manner, by the unusual direction of ideas, or by the state of temper and feelings. If, during this condition of disorder, the ideas should be led to self-destruction, or if any circumstance, whether domestic or public, should occur, which, by exciting the temper or affections, may suddenly increase the cerebral disorder, as well as the consequent morbid ideas or resolution, suicide may be attempted: or if, either after or before the ideas prompting to this act have suggested themselves, the individual should be placed in a state of comparative inactivity, and his ideas be allowed to flow in a direction most likely to suggest or to confirm the resolution to resort to self-murder, the event, although more maturely contemplated, may not be the less certainly accomplished.

618. Suicide, viewed in this direction — the only one in which it can be considered with propriety as a physical disease, — may be attempted by the strongest and most accomplished minds; although much less frequently than by others educated without just principles, and undisciplined in the school of difficulty, disappointment, and misfortune. It is, under these circumstances, like other mental alienations, the result of vascular disorder in an organ intimately connected with the intellectual and moral manifestations. We cannot, therefore, be surprised that persons, subjected to the most important and harassing duties, and undertakings, and anxieties, should suffer in that organ which is the medium or instrument of these distracting operations; and that the consequences resulting from them, both to the organ itself, and to the faculties related to it, should be exactly those, which these causes are most likely, both from theory and experience, to produce.

619. C. *Is there a Suicidal Monomania?*—M. Andral remarks, that " man is sometimes possessed by a sentiment which tends to self-destruction. This feeling is designated '*Suicidal Monomania.*' It is not always the result of mental alienation: some persons put an end to their existence, who are not monomaniacs," &c. Now, this is a contradiction both in terms and meaning, not very consistent with the reputation which this writer has obtained in this country. After what has already been stated, it will be evident that suicide is either the result of some form or other of general or partial insanity; or of some state of excessive passion or feeling, which does not, in the usual acceptation of the term, amount to insanity, — although such passion or feeling may, at the moment, as completely overpower reason and self-control, as any form of monomania. If moral insanity, which I have described above, as constituting a form of partial insanity, be further ex-

tended than I have ventured upon, — and, instead of being confined to those moral states of aberration, which either are slowly developed, or are pertinaciously entertained, or both, be made to comprise those momentary states of excessive passion or feeling, which are suddenly excited by intense moral causes, and which, in well regulated minds, soon subside, without any very appreciable impairment of reason and self-control, but which, in impressible minds unaccustomed to control, to disappointments, to losses, and distraction, often give occasion to insanity or suicide, — then those cases of this act, that thus originate, and that seem the least of all dependent upon insanity, may be considered as actually the result of the insane state; and to these, the term suicidal monomania, or any other equally expressive of the insane condition, may be applied. But, if we thus extend the meaning of moral insanity, we must stretch it still further, and make it comprise also every act of passion or anger, — even the act of just indignation roused by insult; especially when insult is repelled by a retributive blow which may endanger the life of the aggressor. It may be granted that, in a few cases, suicide is the first symptom of insanity; the patient having been previously undisordered in mind. But this is an assumption rarely admitting of proof, unless where the act has been attempted only, and not carried into effect, — other insane acts being afterwards committed. M. ANDRAL, as just noticed, admits that persons destroy themselves as the result of other circumstances than the want of reason; and yet he terms suicide thus occasioned, a form of partial insanity, and designates it "suicidal monomania." Self-murder may depend upon many grades of insanity, and may, as I have shown, be the consequence of the several forms of moral insanity; but, when no degree of this malady is manifest beyond this act, it would be more correct to view it as the consequence of intense passion or feeling, — the impulse to self-destruction arising out of these emotions overpowering, for the moment, the dictates of reason, and the control of the judgment. According to this view, the term here used may still be said to be appropriate; and it may be allowed to be so, if the word insanity be extended to the utmost, so as to comprise the momentary impulses of passion, feeling, and mental depression. Suicide committed, or even attempted, in such circumstances, may then be viewed as a proof of insanity, or be considered as a form of moral insanity, or, as M. ANDRAL has done, with various contradictions of himself, as a monomania, — the aberration of mind consisting only of the impulse to self-destruction. If, on the other hand, *insanity* is to be viewed in a less comprehensive sense, — if it is *not* to be extended to those momentary impulses of excited or depressed passion and feeling, which lead to acts of violence against others or ourselves, and which only for a time overpower reason and judgment, — then suicide committed or attempted in the circumstances referred to, cannot be justly viewed in the above light; but should be looked upon as an act of passion, that, like other violent acts, cannot, consistently with good morals, or even with the safety of society, be treated as an insane act. In the forms of moral insanity noticed above (§ 69. *et. seq.*), it has been shown that, in addition to its more or less gradual developement, the moral aberration is generally pertinaciously adhered to; and that, when suicide follows, the connection of this act with such aberration, and with impairment of the mental powers, is very obvious: but, where disorder of the moral manifestations, or of the judgment, is not apparent, suicide being attempted, from a desire to escape the punishment of crime, or from humiliations of any kind, or from intense passion, distraction, or depression suddenly excited — from some moral shock, the dependence of this act upon a state of mind actually insane is not so manifest; and it will be to the benefit of the community not to consider it, in such circumstances, as the result of insanity. Numerous instances have been recorded, of persons who have had recourse to suicide from imitation or fascination — from the mental infection, caused by the self-murder of some one, however little noted for station, or character. In such cases, a predisposition to this crime may have already existed, or circumstances may have occurred to favour the suggestion of ideas of self-destruction; the suicidal disposition being confirmed, or determined, by perusing the details of this act generally so lavishly furnished by the daily and weekly prints. In some of those occasions of imitative or epidemic suicide, the moral infection has been arrested by inflicting unusual indignities on the bodies of those who perpetrated the crime; thereby showing that this act was not, as respected many of the cases which occurred in these circumstances, altogether the result of the absence of reason, or that the persons who had committed it could not be accounted irresponsible agents.

620. iv. PROGNOSIS. — The suicidal determination is generally removed with difficulty; and more especially when it is consequent upon any of the forms of moral and partial insanity, or is connected with chronic mania. In the advanced stages of melancholia particularly, as well as in several other states of both partial and general alienation of mind, the determination to commit suicide may be concealed, frequently in so artful a manner as to lull the suspicions of the most careful attendants; but it is never removed, unless the mental disorder, of which it is the associate, be altogether cured; and even in this latter case, the incipient return of insanity, or even the occurrence of some of the symptoms usually preceding its return, may be attended by the suicidal attempt. When suicide, however, is the consequence of violent passion and feeling, — of some shock which the mind is incapable of enduring at the time, — when it proceeds from temporary causes, and more especially where the attempt has been made when the mind has been subjected to the first impression of the *direct occasional causes* (§ 611.), and when the *predisposing causes* are not powerful, nor retain their influence in the mind, — then well grounded hopes of the removal of an inclination to suicide may be entertained. When this act has been attempted from causes favouring an unusual determination of blood to the head, or erethysm of the capillary circulation of the brain, — as violent mental excitement, controversy, distraction, or intense mental exertion, the violent shocks of revolution, or the collision of opposing parties, &c., — then an appropriate physical treatment — especially that directed to the removal of increased action in the brain, and of interrupted secretion and excretion — will generally

also remove every disposition to a repetition of the attempt; unless, indeed, similar exciting causes again come in operation. In all cases of attempted suicide from powerful passion or feelings, the possibility of some form of insanity, particularly melancholia and mania, being soon afterwards developed, should be anticipated — and the more especially, if mental disorder, or a suicidal propensity, has appeared in any of the members of the patient's family. In families thus circumstanced, the suicidal attempt is sometimes the first manifestation of insanity.

621. v. TREATMENT.—The treatment of a suicidal disposition, in most cases, and especially in those which are connected with the more obvious manifestations of partial or general insanity, is to be conducted on nearly the same principles as have been explained with reference to these states of disease. In such cases, the suicidal determination is only a part of the disorder, requiring the increased care of the attendants, and greater caution on the part of the medical advisers, particularly during apparent convalescence and recovery; and the strictest precautions against a return of the malady, and upon the appearance of symptoms usually preceding this occurrence; but in other respects demanding little or no modification of the physical and moral means of cure, already advised for the several forms of mental disease. The few observations, therefore, which it will be necessary to offer on the treatment of the suicidal impulse or disposition, may be divided into those which refer — 1st, to the careful removal of the circumstances which suggested or occasioned it; — 2dly, to the physical means which should be resorted to; — and, 3dly, to the preservative measures, or means of repression, moral and legislative, which may be instituted.

622. *A.* The *avoidance or removal of the circumstances or causes*, which suggested or occasioned the suicidal attempt, is the basis on which both physical and moral means of cure must necessarily be placed. This end, however, cannot always, or even generally, be attained; particularly where certain events have produced a powerful or morbid impression on the patient's mind; or where the attempt has proceeded from an insane delusion. Under the former circumstances, we can only endeavour to counteract, or to weaken, the emotion produced: in the latter case, the delusion will disappear only upon the removal of the mental disease. A knowledge of the several occasions of the suicidal determination will sometimes enable the physician to recommend means to neutralise their injurious influence, even when he finds that the patient is incapable of escaping from their baneful influence on his mind.

623. *B.* The *physical means of cure* should be directed chiefly with reference to the symptoms indicating the condition of the circulation in the brain, and the state of organic nervous power. These symptoms should be carefully investigated, and considered in connection with the phenomena more intimately connected with the suicidal impulse, and with mental disorder. If the impulse has followed any of the states of moral insanity, or melancholia, or other forms of alienation, the treatment, physical and moral, is altogether the same as already described; stricter precautions during the treatment, and upon the restoration of the patient to society, being requisite. In many of these cases, particularly those depending upon melancholia, and where the suicidal determination has appeared in consequence of the circumstances which have been shown generally to occasion increased action of the cerebral vessels, and of violent passion, chagrin, or distraction, general or local *vascular depletion*, *purgatives*, *refrigerants*, and *derivatives* are requisite. The pain, tension, or constriction, and uneasiness so frequently experienced in the head; the disordered action of the carotids and cerebral vessels, and the appearance of the eyes; the temperature of the scalp; and the changes frequently observed after death, — all evince the propriety of repeated bloodlettings, especially in the immediate vicinity of the brain, or of the hæmorrhoidal vessels. Cold affusions on the head, cold applications, the shower bath; purgatives conjoined with sedatives and repressants; refrigerants with diaphoretics; occasionally powerful or deobstruent cathartics, and sometimes emetics; anodynes with antispasmodics; dry cupping, setons, blisters, or other derivative applications on the nape of the neck, or on the hypochondria; and, after depletions and deobstruent evacuants, restoratives and tonics, — constitute, in such cases, the chief physical means of cure; but they require to be varied appropriately to the peculiarities of individual cases, and to be aided by hygeienic and moral measures, according to the circumstances or motives occasioning the suicidal attempt, and the form of insanity of which it may have been a manifestation. In most instances, however, exercise in the open air, manual and mental occupations, travelling, active amusements, hunting and horseback exercise, visiting watering places, &c., living in a dry and equable atmosphere, change of air and of scene, and the moral influences (§ 500. *et seq.*) already fully described, should be brought in aid of the more strictly medical agents.

624. After vascular depletions, where they are indicated, *emetics*, even a repetition of them, are often of great service, where the suicidal propensity has recently appeared; and, if much biliary disorder is present, a dose of *calomel*, followed by *stomachic purgatives*, and subsequently by *restoratives* and *antispasmodics*, as the preparations of valerian, will often be useful. *Warm bathing*, and cold sponging the head during the bath, or the *cold affusion* on the head; and the *shower bath* every morning, the feet being immersed in warm water; are also important, and generally appropriate remedies. The suicidal determination is very frequently associated with, and sometimes the consequence of, prolonged sleeplessness, arising from the remote causes of the mental affection. In these cases, a recourse to *narcotics* becomes requisite; the selection and combination of them, as well as the particular indications connected with the use of them, being guided by the principles already explained (§ 475. *et seq.*)

625. *C. Surveillance and restraint.*—Whenever a suicidal propensity appears, the disease should be treated, as respects *seclusion* and *control*, in every respect as above recommended (§ 388. *et seq.*); and the patient be placed in the charge of an experienced and vigilant attendant. Care should be taken to remove from his person and apartment, every article, by means of which he may carry his design into execution; and the windows, doors, &c. should be secured. Even

the bed-clothes should be carefully examined, lest portions of them should be torn off, for the purpose of self-strangulation. Although melancholic and other insane persons are not so likely to attempt suicide when others are present, as when alone; yet, the former circumstance is not always sufficient to deter them from it. Dr. BURROWS adduces an instance, in which a medical man, whilst another person was present, attempted to open the femoral artery with a penknife. His father and grandfather had both destroyed themselves. He had never met with any circumstance to occasion him particular disquietude; but, at the age of forty-five, he became dyspeptic, low-spirited, and listless. He expressed extreme sorrow for the attempt on his life; yet, in three or four days, he seized a razor from the dressing table, whilst his keeper's back was turned, and at one stroke divided one of the carotid arteries.

626. A person who has once entertained a suicidal propensity, should not be confided in, however strongly he may express his regrets at having made an attempt to carry it into effect, as long as the feelings continue, either more than usually blunted, or morbidly sensitive, — whilst the bearing of the patient continues embarrassed or perturbated, or his ideas confused, unsettled, or disturbed. If he complain of heats and flushings in various parts of his body, or partial sweats; and especially if his nights are sleepless; if he cannot look the person whom he addresses fully in the face with a firm expression; and if his eyes betray timidity, fearfulness, distrust, and restlessness; — other attempts will be made. Although the patient may have recovered his serenity of mind, a return of these indications ought to call for the most watchful solicitude from the medical and other attendants; for, although the patient may not seem to entertain any ideas of suicide, or may actually not feel any inclination to commit the act, yet the occurrence of an opportunity, or the accidental sight of an instrument of self-destruction, may give rise to the impulse, which may instantly be carried into fatal effect.

627. Whenever a great calamity has overtaken a person of weak resolution, of the melancholic, nervous, or irritable temperament, and especially if insanity or suicide have occurred in any branch of his family, — particularly if the affliction is sudden or recent, and productive of great mental distress, or of singularity of conduct or conversation,—the probability of his attempting suicide ought not to be overlooked. The design, however, in these circumstances, may be concealed from superficial observers; but the physician will detect, in the expression of the eyes and looks, in the suppressed struggle to conceal his emotions, in the constrained respiration, and the accelerated, excited, or irregular pulse, sufficient causes to require the utmost vigilance on the parts of both friends and attendants. In such cases, the previous character and fortitude of the patient may lull every fear; but the greatest talents, and the strongest minds, have yielded to intense emotion. The moral character and disposition of the patient may have been changed, before the suicidal propensity was developed; many of the circumstances, to which this propensity had been directly imputed, actually occasioning a state of moral or partial insanity, of which the suicidal intention was only an attendant or consequence. Moreover, character and disposition only should not afford any grounds of confidence in persons subjected to the more intense emotions, or to the more energetic occasions of this act; more especially if they have not formerly experienced events requiring the exertion of mental energy and fortitude. Many men, eminent for talent and excellence of disposition, have committed suicide, when overtaken by adversity. Several instances of this kind occurred, during an early part of the present century, in this country; and have been adduced by some writers, as proofs of the strongest minds being liable to give way to the suicidal impulse. But eminence and talent are distinct from fortitude in adversity; and even from that constitution of mind, to which the terms strength of mind or force of character have been applied. It is doubtful how far these persons were really possessed of these latter characteristics; inasmuch as they are usually acquired, in combating difficulties, in patiently bearing adversity and disappointments, and in controlling the more poignant emotions which difficulty and adversity call forth. In this school, where true force of character and fortitude are chiefly, if not only, to be acquired, these persons may not have been sufficiently disciplined; for, when the course of prosperity has been uninterrupted and rapid, however eminent the abilities which have contributed to it may have been, sudden adversity may endanger the perfect sanity or fortitude of a mind, unaccustomed to sustain, and unprepared to meet, its shock.

628. There is no part of a physician's duty which is so difficult, as Dr. BURROWS has remarked, as to decide upon the exact time when he may place confidence in a convalescent suicide. If this confidence be yielded prematurely, the act, which time and great care had been employed to avert, may be immediately perpetrated; whilst, if it be withheld when the patient feels that he has been labouring under a delusion, the effect may be such as to endanger a return of his delusion, or of the suicidal propensity.

629. When the suicidal determination cannot be carried into effect by any other means, owing to the care of the attendants, the patient sometimes determines to starve himself. Management may do much in overcoming this intention. Kind entreaties and stratagems may be resorted to; and tempting articles may be set before him, or left within his reach, without any further notice. If he partake of it, no remark should be made, but the same course pursued. If these means fail, the stomach-pump ought to be resorted to.

630. M. FALRET observes, that noisy or immoderate gaiety irritates melancholic suicides, or, at best, affords only a transient pleasure, followed by increased misery. He states, that he has accompanied these persons to the theatre, and to the hospitals, in order to compare the effects produced upon them by these opposite spectacles; and he has found, that visits to the really afflicted were most useful, by suggesting the idea, that others had still greater cause than they of being unhappy.

631. *D.* PREVENTION AND REPRESSION. — The increasing frequency of suicide, as well as of manifest insanity, requires some notice of the means by which it may be, in some measure, repressed, although no sanguine hopes of success from them can rationally be entertained in the present states

of society. As long as education, manners, morals, and social intercourse continue as they now are — as long as crimes, murders, and suicides are seductively detailed and daily furnished to the public, through a thousand channels, for the purposes of private gain — as long as the perpetrators of crimes and of homicides are held out, both on the stage and from the press, as heroes of their day — as long as the overthrow of moral and religious principles, and the infection or contamination of the public mind, are made objects of gainful speculation, into which persons in place or authority are not considered dishonoured by entering — as long as the streams of moral pollution are allowed to flow without either strenuous, or well-directed, or combined efforts to confine or to counteract them — as long as the most instant and efficient agents of self-destruction are openly sold in every street, at little or no price, and to any purchaser, without either "let or hindrance" — as long as the struggles of great parties in politics and religion absorb, in connection with the details of every vice and every crime, the public mind, each party endeavouring to depress and ruin the others, without regard to the general weal — as long as provision for the pecuniary wants of the state, and the power and patronage of office, constitute the chief objects of governments — as long as justice is within the reach only of the wealthy, as laws protect chiefly the bad, as the weak are unshielded, and the deserving unrewarded — as long as

—— "The whips and scorns of time,
The oppressor's wrong, the proud man's contumely,
The pangs of despised love, the law's delay,
The insolence of office, and the spurns
That patient merit of the unworthy takes,"

shall continue to "puzzle the will" — as long as the lives of all classes are endangered, and their minds distracted, by unprincipled and ignorant pretenders to medical and religious knowledge, who are allowed, and even encouraged, to take advantage of the credulity and fears of the weak-minded — as long, in short, as moral degradation and physical destitution exist, and as long as the safety of the people is *not* the supreme law of the state — as long as these several conditions of a country continue, and in proportion to their separate and combined influence — so long will suicides be frequent or even increase.

632. The history of all nations has demonstrated the prevalence of this act, both as a disease and as a psychological phenomenon, during periods of surpassing luxury, of criminal debasement, of public commotion*, and of the decline of public and private spirit and virtue. In such circumstances, laws directed simply to this act, and without reference to the sources of the evil — to the various contaminating moral agents, poisoning the minds of the community — will be of but little avail. It is obvious, that laws which, as at present, affect only the property of the suicide, are unjust, as they cannot punish the guilty, but fall exclusively on the innocent — on those already punished by the act of the suicide. The only means of *prevention* which have been found to succeed, on occasions of epidemic or imitative suicides, have been such as tended to impress the ignorant with the moral and religious turpitude of the act, to influence public opinion in its reprobation, and to convince the perpetrator of the crime, that, although he escapes from feeling the punishment it merits, every indignity, which is compatible with the good of society, will, as a consequence, be offered to his body, and to his memory. Each member of the community lives not for himself alone, but for the common weal, and in order to contribute to the general, the mutual, the public, and the private support, requisite to the healthful constitution of society. As it is the chief purpose of good government to preserve inviolate this principle of existence in all associated communities, so ought every effort to contravene it, or to escape from the responsibilities it involves, to be repressed and punished in ways the most effectual, conformably with the spirit in which only should punishment be inflicted; and even those, who either directly or indirectly aid in the commission of this act, should be subjected to punishment. The difficulty, however, is to determine upon measures which may have any influence in diminishing the number of suicides, who are either irresponsible agents, or are in that state of mind which is uninfluenced by worldly considerations. There is every reason to believe, nevertheless, that many of those who commit this act without being manifestly insane — who entertain a suicidal propensity from depression of spirits; from mortified pride; from domestic chagrin or irritation; from excessive passion or feeling; from imitation, fascination, or mental infection; from extreme profligacy, debauchery, and satiety, &c., — would be deterred from it by the conviction that, if they perpetrated this crime, some indignity to their bodies, and disgrace to their memories, would be the result. If it were enacted that the body of a suicide, who had not evinced sufficient proof of previous insanity to require restraint, or whose relations had not seen sufficient proof of mental disorder to obtain medical aid, or other assistance requisite to the protection of others as well as of himself, should be made subservient to medical instruction, and consequently to the general weal, — I am confident that the number of suicides would diminish, notwithstanding the increased, and increasing, sources of mental contamination, and of mental disease. Means of repression directed to the property of a suicide would have little avail, and would, moreover, punish the innocent, without affecting the guilty; but such means ought to be strenuously directed against those who deal in poisonous substances, and ought to be rendered so stringent as entirely to prevent such substances from being procured unless by means of a physician's or surgeon's order or prescription. It is well known, that suicide is often committed in moments of irritation or passion, and that as soon as the feeling subsides — in the course even of a few minutes — the suicidal impulse or intention may cease to influence volition so powerfully as to lead to the commission of the act. Therefore, if difficulties were thrown in the way of resorting to it, during periods of irritation and suicidal impulse, it might not afterwards be entertained, or the sober mind would recoil with so great horror

---

* In the summer of 1793, upwards of 1300 suicides were committed in Versailles and its vicinity! During "the reign of terror," or rather of crime, suicides were committed by the guilty, by the terrified, by infidels, and contemners of moral and religious principles, by public and private criminals, and by those distracted by losses of fortune and friends, in unheard of numbers, throughout France.

from the morbid idea, as to view it with increased dislike, or would endeavour otherwise to fortify or to protect itself against a return of the propensity.

633. Having thrown out these hints as to the only means of repression which can be suggested, after a consideration of those which have been enacted in this and in foreign countries, I would merely add, that the growing frequency of suicide requires that means, direct and indirect, should be taken by the legislature to restrain it. As, however, many of the most influential causes of suicide can only be indirectly affected by legislative measures, and as some of these causes belong to the liberty enjoyed by all classes, although appertaining chiefly to the most worthless parts of that liberty, but little hope can reasonably be entertained that the frequency of this act will be much diminished, — as long, at least, as the circumstances arising out of the education, morals, amusements, and social relations of the community, to which it is in great measure referrible, continue unchanged.

INTESTINE — Syn. Ἔντερον (ab ἐντὸς, intus) — Intestinum (from intus, within). — *Intestin*, *Boyeau*, Fr. *Darm*, Ger. *Intestino*, Ital. — *Bowel*; *Gut*; *Intestinal Canal*; *Intestinal Tube*.

1. Most of the *disorders* and *structural diseases* to which the *intestines*, in general, are liable, are discussed in appropriate articles. The seat and nature of these affections required a separate consideration for them; and, at this place, it remains for me chiefly to supply whatever I may have omitted in these articles, and to treat of those subjects, which have not been entered upon under different and more appropriate heads.

2. It need hardly be stated, that the intestines comprise, or consist of the following parts, descending from the stomach to the verge of the anus, namely, the *duodenum*, the *jejunum*, the *ilium*, the *cæcum*, the *colon*, and the *rectum*. As each of these portions of the intestinal canal presents most important connections with, and relations to, other viscera, that are not possessed to an equal degree, or in a similar manner, by the others; as they are, in many respects, and particularly as regards certain of their functions, distinct organs; and as they are often severally the seats of disorders, more or less limited to either of them, so I have treated of the diseases to which each of these portions of the intestinal canal are most liable, under their respective heads. As there are certain maladies, which affect, in some degree or other, more than one of these distinct portions of the bowels, and which often implicate, or even originate in, some one or more of the collatitious viscera, and in which not only the intestines, but the various related viscera, and even the frame generally, frequently are also disordered, although in different grades and forms, and to a varied extent, according to numerous circumstances connected with the cause of the disease, and state and constitution of the individual attacked, so I have treated of these maladies under the names commonly applied to them, but with strict reference to their seats, natures, and pathological relations. Thus, whilst I have considered the diseases individually seated chiefly in either the *duodenum*, *cæcum*, *colon*, &c., under these heads respectively, I have likewise discussed *colic* and *ileus*, *costiveness* and *constipation*, *diarrhœa*, *cholera*, *dysentery*, *gastro-enteric disease*, *flatulency*, *intestinal hæmorrhage*, *intestinal concretions*, and *worms*, &c., in these several articles, because these complaints are not limited, in their seats, to one portion of the intestinal canal only, but often extend to several portions of it, although in different grades, and frequently depend upon disorder of the adjoining viscera, and sometimes even of distant organs, and of the system in general. Moreover, as the *organic lesions* which occur in the intestines are not peculiar to any one portion, but extend, in different maladies and persons, and in different degrees of frequency and severity, to all of them, and even also to the stomach and œsophagus — to the whole digestive canal from the lips to the anus — so I have considered these lesions under the head "Digestive Canal," and have thereby avoided the repetitions, into which I should otherwise have been betrayed. It here chiefly remains for me to consider those maladies, seated principally in the *small* and *large intestines* — in the *ileum*, *jeju-*

num, and *colon*, — that are not discussed under different or more appropriate heads. The *functional disorders*, and the *structural changes*, to which the *intestines* are liable, being fully treated of in the articles just mentioned, I now proceed to consider chiefly their *inflammatory diseases*. In the article on the *peritoneum*, however, much will be found more or less intimately connected with inflammations of both the small and large intestines, to which sufficient reference will be also made in those sections, where inflammation extending to the peritoneal coat of the bowels, and the complications of enteritis, are considered.

I. Inflammation of the Small Intestines.— Syn. Χόρδαψος, Εἰλεὸς, Aretæus, Galen.— *Febris intestinorum inflammatoria*, Hoffmann. *Intestinorum Inflammatio*, Boerhaave. *Enteritis*, Sauvages, Vogel, Sagar, Cullen, Pinel. *Empresma Enteritis*, Good. *Cauma Enteritis*, Young. *Gedärmentzündung*, *Entzündung der Gedärme*, *E. der Därmen*, Germ. *Entérite*, *Inflammation des Boyaux*, Fr. *Inflammazione d'Intestini*, Ital. *Inflammation of the Bowels*.

Classif. — 1. *Class*, Febrile Diseases; 2. *Order*, Inflammations (*Cullen*). 1. *Class*, Diseases of the sanguineous Function; 2. *Order*, Inflammations (*Good*). III. Class, I. Order (*Author* in *Preface*).

3. Defin. — *Tenderness or pain of the more central parts of the abdomen, increased on pressure, generally with symptomatic fever, disordered defæcation, and frequently nausea and vomiting*.

4. Inflammation generally commences in one only of the constituent tissues of the small intestines, and frequently continues to be thus limited during its course; but it frequently also extends to the other parts, until even all the textures forming a portion of intestine are implicated. Thus the glandular apparatus, or the mucous membrane only may be inflamed, and the disease may not extend further, although it may exist long, or be extremely acute: but it often, also, invades the other tissues, more especially the connecting cellular tissue, until the peritoneal coat is at last inflamed, and all the phenomena of circumscribed or diffused peritonitis is produced. When all the constituent tissues of a portion of intestine are affected, the inflammation usually has commenced and proceeded in this manner; for it is but seldom that there is reason to infer that the inflammation has either simultaneously invaded all the coats composing a portion of bowel, or has proceeded in an opposite direction, namely, from the peritoneal to the other coats; unless, indeed, in cases of external injury, or of strangulated hernia, or when the inflammation has extended from adjoining parts to the intestines.

5. Inflammation of the intestines, whether limited to one only, or implicating two, or all, of their constituent tissues, may assume any grade of *intensity* and *acuteness*, from the *most acute* down to the *slightest degree* and the *most chronic form*. It may appear, in either of these states, as a *simple* or uncomplicated disease, or *associated* with other maladies. In this latter state, it may be either *primary* or *idiopathic*, or *consecutive* or *symptomatic*. In each of the above forms it will be here considered.

6. i. Inflammation of the Mucous Surface of the Intestines.—*Muco-Enteritis*, of Armstrong. — *Muco-Entérite*, *Entérite Villeuse*, of French pathologists. — This complaint varies in its *characters* with its *intensity*, and with the temperament and habit of body of the patient; a slighter grade of it often causing, in irritable, nervous, and plethoric persons, more acute symptoms than a severer degree in those who are melancholic or leucophlegmatic. The *symptoms*, moreover, are further varied by the extension of the inflammatory affection, in some degree to the duodenal or gastric villous surface on the one hand, or to the internal surface of the cæcum and colon on the other; for the mucous coat of the small intestines is inflamed more frequently in conjunction with one or more of these than in an unassociated form; and not infrequently some one of the adjoining viscera is also more or less disordered. Indeed, the enteric disease may be altogether consecutive of, and caused by, derangement of one or other of these viscera. Thus a discharge of acrid or otherwise morbid bile into the duodenum may occasion or perpetuate inflammation of the mucous surface of the intestines, and often also of the large bowels.
